Keywords: Chelating resin Cysteine RSM Adsorption Cu(II)

### ABSTRACT

Polyacrylonitrile beads (PAN) cysteine (CS) was synthesized from polyacrylonitrile beads (PAN) and cysteine (CS). The content of the functional group and the percentage conversion of the functional group of PAN-CS prepared under the optimum condition using response surface methodology (RSM) for the first attempt were 3.22 mmol/g and 35.78%. The structure was characterized by FT-IR and elemental analysis. The adsorption properties of the resin for Cu(II) were investigated by batch and column experiments. Batch adsorption results suggested that PAN-CS had higher adsorption capability for Cu(II) than other metal ions and maximum saturated adsorption capacity was 184.7 mg/g. The resin and its metal complexes were studied by FT-IR. Furthermore, the resin can be eluted easily using 1 mol/L HCl. PAN-CS can provide a potential application for selective removal of copper from waste solution. © 2016 Chinese Chemical Society and Institute of Materia Medica, Chinese Academy of Medical Sciences.

Polyacrylonitrile (PAN) is an ideal polymeric matrix with a

series of merits such as mechanical stability, solvent resistance,

and abrasion resistance [10]. Active nitrile groups (C=N) in PAN

can easily be converted into a number of new functional groups via

special reactions. Deng et al. [11–13] used aminated polyacryloni-

trile fibers to remove copper, lead, and chromium ions from

aqueous solutions; however, the adsorption capacity was not high,

and selectivity was not mentioned. Our initial report showed that

the cysteine functionalized polyacrylonitrile resin can be used for

selective adsorption of Cu(II) from solutions with a good

and mathematical techniques which has been successfully used

grafting cysteine on the surface of PAN beads, which has promising

potential for the application of the separation and preconcentra-

tion of Cu(II) from multicomponent solutions. The synthesis

conditions such as reaction temperature, molar ratio of reagents,

and reaction time have been optimized with the use of RSM. The

synthetic resin was characterized by FT-IR and elemental analysis

(EA). The resin was designed to fit in with environmental

for developing, improving, and optimizing processes [14].

Response surface methodology (RSM) is a collection of statistical

In this work, we designed a novel chelating resin (PAN-CS) by

## 1. Introduction

Copper is a nonferrous metal largely applied in industry for the production of various conduction parts of cables, electrical units, and jewelry. It serves as a component of different alloys, and is also used as catalytic agents. Meanwhile, copper is known as a trace element necessary for life; however, the excessive intake of heavy metals causes significant harm to human health. Since heavy metal pollution has made a great impact to environment in recent years, development of novel methods to remove and reuse copper from waste disposal is vital to the environment for alleviating issues of copper pollution [1-8]. Recently, adsorption has been considered one of the most popular and effective methods for the removal of pollutants at different industrial facilities and from different natural environments. Because adsorption is an interfacial phenomenon, it has certain qualities, such as fast kinetics, flexibility in design, and mild regeneration condition [9].

### 52 2. Experimental

### 53 2.1. Materials

54 Mesoporous-type cross-linked polyacrylonitrile beads (PAN), 55 cross-linked with 7% divinylbenzene (DVB), nitrogen content 56 22.18%, functional groups content 15.83 CN mmol/g, specific 57 surface area 27.8 m<sup>2</sup>/g, pore size 25.1 nm, were purchased from 58 Chen Guang Chemical Industrial Institute of China. Cysteine was 59 purchased from Aladdin Industrial Corporation, China. Aqueous 60 solutions of ions at various concentrations were prepared from 61 NiSO<sub>4</sub>·6H<sub>2</sub>O, HgCl<sub>2</sub>, CuCl<sub>2</sub>·2H<sub>2</sub>O, Zn(NO<sub>3</sub>)<sub>2</sub>·6H<sub>2</sub>O, Cd(NO<sub>3</sub>)<sub>2</sub>·4H<sub>2</sub>O, 62 and Pb(NO<sub>3</sub>)<sub>2</sub>, and were used as sources for Ni(II), Hg(II), Cu(II), 63 Zn(II), Cd(II), and Pb(II), respectively. All other reagents and 64 solvents were of analytical reagent grade and were used without 65 further purification.

### 66 2.2. Apparatus

67 IR spectra for the samples were obtained from a Nicolet 68 380 Fourier transform infrared (FT-IR) spectrometer. The concen-69 trations of metal ions were measured by Inductively Coupled 70 Plasma Optical Emission Spectroscopy (ICP-OES). C, N, and S 71 elements were analyzed by a Vario EL III Elemental Analyzer. The 72 specific surface area and the mean pore size of the resins were 73 determined on an Autosorb-1 automatic surface area and pore size 74 analyzer. A Mettler Toledo delta 320 pH meter was used for pH 75 measurements.

### 76 2.3. Preparation of PAN-CS

77 The preparation procedure is simple and described as follows: 78 PAN beads and N,N-dimethylformamide (DMF) were added into a 79 three-neck round-bottom flask, swelling overnight. Then, CS and a 80 small amount of metallic sodium used as catalyst were added to 81 the flask. The mixture reacted with 100 rpm stirring speed under a 82 nitrogen atmosphere. The solid product was carefully washed 83 thoroughly with DMF and deionized and then washed with 84 acetone and ether. After that, the obtained resin was dried in 85 vacuum at 50 °C. The conversion of the functional group of the 86 synthetic resin can be calculated from the nitrogen content by the 87 following equations:

$$F_c = \frac{N_c}{14 \times n_c} \times 100$$

99

88

91 
$$X = \frac{F_n \times 1000}{1000 \times F_0 - \Delta m \times F_n \times F_0} \times 100\%$$

92 where  $F_0$  (mmol of Cl/g) and  $F_c$  are the contents of the functional 94 group of polystyrene and the synthesized resin, respectively, X is 95 the functional group conversion (%), *m* is the incremental synthesis 96 reaction resin (g/mol),  $n_c$  is the number of nitrogen atoms of ligand 97 molecules, and  $N_c$  is the nitrogen content of the synthesized resin 98 (%).

### 99 2.4. Resin adsorption and desorption experiments

100Batch experiments were carried out to investigate the Cu(II)101adsorption property on the prepared PAN-CS resin by placing10215.0 mg resin in a series of flasks containing 30 mL of the studied103metal ions at the desired initial concentration and pH. Then, the104contents of the flasks were shaken in a flask-shaker at specific105temperatures for a given time with a speed of 100 rpm. The106residual concentration of the studied metal ions in the solution was

determined by ICP-OES. The adsorption capacity (Q, mg/g) and<br/>distribution coefficient (D, mL/g) were calculated with the<br/>following expression:107109110

$$Q = \frac{C_0 - C_e}{W} V$$

$$D = \frac{C_0 - C_e}{WC} V$$
113

where  $C_0$  is the initial concentration of Cu(II) (mg/mL),  $C_e$  is the 114 residual concentration of Cu(II) in solution (mg/mL), V is the 116 solution volume (mL), and W is the resin dry weight(g). 117 Desorption experiments were carried out following the comple-118 tion of the adsorption experiments. After adsorption experi-119 ments, the resins were separated from the aqueous solution by 120 filtration, washed with deionized water, and shaken with 121 different eluent solutions of various concentrations at 298 K 122 for 24 h. After that time the concentration of Cu(II) was similarly 123 analyzed as described above. After each adsorption-desorption 124 cvcle, the resin beads were washed and reconditioned for 125 adsorption in the succeeding cycle. The desorption ratio (E) 126 was calculated as follows: 127 128

$$E(\%) = \frac{C_d V_d}{(C_0 - C_e)V} \times 100\%$$

where  $C_d$  is the concentration of the solutes in the desorption120solutions,  $V_d$  is the volume of the desorption solution, and  $C_0$ ,  $C_e$  and131V are the same as defined above.132

### 3. Results and discussion

3.1. Analysis of variance (ANOVA) and development of regression model equation

Experimental data obtained using the Design Expert 8.0.4 soft-136ware for multiple regression equation, and gained objective137function quadratic regression equation on the conversion rate of138the functional group of PAN-CS:139

$$Y = 43.28 + 1.43A - 1.44B$$

 $+\,2.27C-1.45A2-0.49B2-2.29C2-1.38AB+0.18AC-0.54BC$ 

The results for analysis of variance for quadratic regression are 143 given in Table 1. From the analysis results in Table 1, the overall 144 model is highly significant ("Pr > F" value <0.0001), no significant 145 lack of fit items ("Pr > F" value = 0.7348 > 0.05), which is desirable. 146 The model can be used to predict the conversion rate of the 147 functional group of PAN-CS for different conditions. The determi-148 nation coefficient  $R^2 = 0.9840$ , and the coefficient of variation 149 (C.V%) 1.27% is within an acceptable range, which indicates that the 150 experiment as described is operable. The adjusted R-square 151  $R_{\rm adi}^2 = 0.9635$ , demonstrates 96.35% of the variability of the data 152 can be explained by the model. Adeq Precision is to detect a noise 153 signal ratio and it is operable once the ratio is over 4. The 154 experimental Adeq Precision is 19.072, which is moderate, 155 156 indicating that this model can accurately predict the experimental results. It is seen from the F value of each single factor that the 157 molar ratio has the most significant impact on the conversion rate. 158 Compared with the single factor experimental results, which found 159 160 that the molar ratio within a certain range has the greatest impact on the conversion rate; the effects of time and temperature were 161 not significant ("Pr > F" value > 0.05). 162
