### 1. Introduction

The era of fluorine chemistry began with the synthesis and successful isolation of elemental fluorine ( $\text{F}_2$ ) by Henri Moissan in 1886.<sup>1</sup> Within more than a century's development, especially in the past few decades, a large number of effective approaches for the introduction of fluorine atoms into widely used synthetic frameworks have been extensively exploited.<sup>1,2</sup> Fluorine has the strongest

electronegativity (4.0 in Pauling scale) and a small atomic size ( $r_V=1.47 \text{ \AA}$ ).<sup>1</sup> The C–F bond formed between fluorine and carbon is slightly longer than the C–H bond, but the bond energy of the former is much higher than that of the latter.<sup>3</sup> Fluorine is more similar to oxygen than to hydrogen in terms of electronic properties;<sup>1,3</sup> it can be used as a functional bioisostere of oxygen.<sup>1a,4a</sup> These unique 'fluorine effects' render enhanced biological activities of fluorinated bioactive molecules and fabulous physico-chemical properties of fluorine-containing materials.<sup>1</sup>

Among fluorine-containing functional groups, the trifluoromethyl moiety ( $\text{CF}_3$ ) is one of the most prevalent groups in

design of new pharmaceuticals and agrochemicals because its incorporation into drug candidates can dramatically change their metabolic stability, lipophilicity, bioavailability, and the protein bind affinity.<sup>1</sup> The CF<sub>3</sub> group is an electron-withdrawing group and has a significant influence on the pK<sub>a</sub> values of the neighboring functional groups, such as alcohols, carboxylic acids, and amines, which result in 'special' properties.<sup>1,4a</sup> Despite fluorine is the most abundant halogen and ranks the 13th most abundant element in the earth's crust, there are no naturally occurring CF<sub>3</sub>-substituted compounds and all the target CF<sub>3</sub>-containing compounds are without exception artificially synthesized. Therefore, the development of efficient methods to introduce CF<sub>3</sub> group into organic scaffolds has become one of the hottest topics in organic synthesis today.<sup>2,4,5</sup>

The direct trifluoromethylation reactions have been confirmed to be the most important and promising methods to construct C–CF<sub>3</sub> bonds among the widely used approaches.<sup>1,2,4,5</sup> Traditionally, the direct trifluoromethylation includes the reactions of electrophiles with nucleophilic CF<sub>3</sub> reagents, nucleophiles with electrophilic CF<sub>3</sub> species, and radical acceptors with CF<sub>3</sub> radical precursors. It is remarkable that the direct trifluoromethylation of nucleophiles with nucleophilic CF<sub>3</sub> reagents and electrophiles with electrophilic CF<sub>3</sub> sources have also been accomplished. The reactions proceed through oxidative-trifluoromethylation mechanism<sup>5g</sup> and reductive-trifluoromethylation pathways,<sup>6</sup> respectively. The early examples of reductive trifluoromethylation showed that electrophiles, such as disulfides and aldehydes, can be readily trifluoromethylated by CF<sub>3</sub>X (X=I, Br) or PhSO<sub>2</sub>CF<sub>3</sub> in the presence of reductants like Na, Mg, Zn, and TDAE ([tetrakis(dimethylamino) ethylene]).<sup>6</sup> Although the nomenclature of reductive trifluoromethylation is known,<sup>6</sup> to our knowledge, its definition has never been made. To differentiate these transformations from other types of reactions, we tentatively propose a conceptual model of reductive trifluoromethylation in this report: electrophiles or nucleophiles are trifluoromethylated by CF<sub>3</sub> reagents in the presence of reductants, wherein the reactions start with the reduction of CF<sub>3</sub> sources.

The first metal-mediated reductive trifluoromethylation with electrophilic <sup>+</sup>CF<sub>3</sub>' reagent was reported in 2011.<sup>7</sup> The reaction of aryl iodides (electrophiles) with electrophilic [Ph<sub>2</sub>SCF<sub>3</sub>][OTf] salt in the presence of copper powder gave the corresponding trifluoromethylated products in almost quantitative yields; the CuCF<sub>3</sub> intermediate was determined in the reaction by <sup>19</sup>F NMR and mass spectrometric analysis of the reaction mixture.<sup>7a</sup> Later, Cu(I)-mediated reductive trifluoromethylation of arylboronic acids (nucleophiles) with [Ph<sub>2</sub>SCF<sub>3</sub>][OTf] was performed, and the CuCF<sub>3</sub> species was observed similarly.<sup>8a</sup> The rongalite-initiated bifunctional trifluoromethylation of styrenes (nucleophiles) with [Ph<sub>2</sub>SCF<sub>3</sub>][OTf] was harnessed, as well, and the CF<sub>3</sub> radical intermediate was captured by styrenes.<sup>9</sup> Since then, more trifluoromethylation reactions involving reductive transformation of electrophilic <sup>+</sup>CF<sub>3</sub>' reagents have been reported.

In this review, we summarize the rapid progress of the reductive trifluoromethylation reactions with electrophilic <sup>+</sup>CF<sub>3</sub>' reagents in the past few years, in which either electrophiles or nucleophiles are trifluoromethylated by <sup>+</sup>CF<sub>3</sub>' sources in the presence of proper reductants. The reactions should involve CF<sub>3</sub> radicals, CF<sub>3</sub> anions or related intermediates, which are derived from the reduction of <sup>+</sup>CF<sub>3</sub>' reagents by transition-metals, inorganic salts, photoredox

catalysts or even substrates via single electron transfer processes. The reduction of <sup>+</sup>CF<sub>3</sub>' sources is the initial step that triggers the entire reaction. Although numerous mechanistic discussions and debates have been commenced, the whole mechanisms of the reductive trifluoromethylation with <sup>+</sup>CF<sub>3</sub>' reagents are still unclear (see Sections 2 and 3).

Our report will mainly focus on the transition-metal mediated/catalyzed trifluoromethylation of electrophiles/nucleophiles with electrophilic <sup>+</sup>CF<sub>3</sub>' sources, which comprises CF<sub>3</sub> radicals or metal-CF<sub>3</sub> species, or undergoes other reductive transformation of <sup>+</sup>CF<sub>3</sub>' reagents. The reactions of perfluoroalkyl halides (R<sub>fn</sub>X, e.g., CF<sub>3</sub>I) with reductants (such as Na<sub>2</sub>S<sub>2</sub>O<sub>4</sub> and Zn) and radical initiators (like Bz<sub>2</sub>O<sub>2</sub> (benzoyl peroxide) and AIBN (azobisisobutyronitrile)), which give, respectively, the sulfinate dehalogenated products, the hydrodehalogenated products, the homo-coupling products, and the perfluoroalkylated products via radical or nucleophilic processes.<sup>4b,10</sup> represent a broader concept of reductive perfluoroalkylation reactions and will not be included in this report. We simply classify reductive trifluoromethylation reactions with electrophilic <sup>+</sup>CF<sub>3</sub>' reagents, according to the type of CF<sub>3</sub> reagents, into two parts (see Sections 2 and 3). In each part, the debates related to the transformations are also described.

## 2. Reductive trifluoromethylation reactions with Umemoto's reagents and their analogs

### 2.1. Electrophilic Umemoto's reagents and their analogs

Because of the strong electronegativities of R<sub>fn</sub> groups (e.g., CF<sub>3</sub>: 3.45 in Pauling scale), R<sub>fn</sub>X (R<sub>fn</sub>=perfluoroalkyl, X=I, Br, Cl) and even R<sub>fn</sub>OTf (OTf=OSO<sub>2</sub>CF<sub>3</sub>) do not undergo electrophilic perfluoroalkylation; the nucleophiles attack the halogen atoms (X) of R<sub>fn</sub>X or the sulfur center of OTf group rather than the R<sub>fn</sub> groups.<sup>11a-b</sup> Significantly, in the 1970s and 1980s Yagupolskii and co-workers synthesized (perfluoroalkyl)-aryliodonium salts and (perfluoroalkyl)chalcogen salts (including <sup>+</sup>CF<sub>3</sub>' salts), and found that these compounds can be used as electrophilic perfluoroalkylation reagents.<sup>11c-e</sup> Since this pioneering work, the design and synthesis of novel electrophilic <sup>+</sup>CF<sub>3</sub>' reagents have been widely investigated (Scheme 1).<sup>11a,b</sup> S-(trifluoromethyl)dibenzothiophenium tetrafluoroborate and triflate (Umemoto's reagent, **1b–c**) and S-(Trifluoromethyl)diarylsulfonium triflate (Umemoto-Shreeve reagent, **1d**), developed by Umemoto, Shreeve, and so on, are the most widely used chalcogenium salts for effective electrophilic trifluoromethylation of a wide range of nucleophiles.<sup>1,2,4,5,11,12</sup> S-(Trifluoromethyl)thiophenium salts (expanded Yagupolskii-Umemoto-type reagents or Shibata's reagents, **1e**), prepared from triflic acid-catalyzed intramolecular cyclization of *o*-ethynylaryl-trifluoromethylsulfanes, have also demonstrated to be promising trifluoromethylation reagents for  $\beta$ -ketoesters and dicyanoalkylidenes.<sup>13</sup>

The Umemoto's reagent (**1b**) was initially described as a pure electrophilic <sup>+</sup>CF<sub>3</sub>' source since it could form CF<sub>3</sub>SO<sub>3</sub>CF<sub>3</sub> (**2**) in high yield by pyrolysis (Scheme 2).<sup>14</sup> However, in the same article, the authors recognized that the reaction may occur via a bimolecular ionic substitution and/or a free radical chain mechanism, which is dependent upon the nature of the nucleophiles.<sup>14</sup> The kinetic study later disclosed that the cyclic Umemoto's reagent (**1b**) has higher reactivity than the non-cyclic Umemoto-Shreeve reagent (**1d**).<sup>15</sup> The critical difference in chemoselectivity of reactions between S-(methyl)dibenzothiophenium salt (**6**) and **1b** with aniline (N-methylation vs C-trifluoromethylation, Scheme 3) was indicative of a mechanism different from a classical S<sub>N</sub>2 process, despite their respective CH<sub>3</sub> and CF<sub>3</sub> groups adopting similar orientations in the crystal structures.<sup>15,16a</sup> The Mulliken population analysis of S-(trifluoromethyl)dibenzothiophenium cation (**8**) indicated a positive
