Conformational analysis

Pyrophosphate analogs

ABSTRACT

The preparation and reactivity of some α,α -difluorophosphinates are investigated. Alkylation of *H*-phosphinates with LiHMDS and ClCF_2H gives the corresponding α,α -difluorophosphinates in good yield. Deprotonation of these reagents with alkyllithium or LDA is then studied. Subtle electronic effects translate into significant differences in the deprotonation/alkylation of the two 'Ciba-Geigy reagents' $(\text{EtO})_2\text{CRP}(\text{O})(\text{OEt})\text{H}$ ($\text{R}=\text{H}, \text{Me}$). On the other hand, attempted methylation of difluoromethyl-octylphosphinic acid butyl ester resulted in the exclusive alkylation of the octyl chain. Finally, reaction with carbonyl compounds results in the formation of 1,1-difluoro-2-phosphinoyl compounds.

1. Introduction

α -Fluorophosphorus compounds have gained popularity as potential pharmacophores. In the case of phosphonates, the fluorine substituent(s) is known to modulate the pK_a of the phosphonic acid group, sometimes improving the mimicry of a natural phosphate monoester, and the inhibitory potency of the resulting analog.¹ α,α -Difluorophosphinates have been much less studied, and in their case, the effect of fluorine on the pK_a is unimportant since the phosphinic monoacids are always deprotonated at physiological pH. Nonetheless, the CF_2 moiety is a known mimic of an oxygen atom. Using our radical hydrophosphinylation reaction (NaH_2PO_2 , $\text{Et}_3\text{B}/\text{air}$)² Piettre and co-workers have pioneered the synthesis of α,α -difluorophosphinates, from 1,1-difluoro-2,2-disubstituted olefins (Eq. 1).³

Fifteen years ago, Hall and co-workers reported the only example we could find of the base-promoted alkylation of a difluoromethylphosphinate $\text{RP}(\text{O})(\text{OEt})\text{CF}_2\text{H}$, as well as its subsequent elaboration into

a GABA analog (Scheme 1).⁴ Two GABA analogs $\text{H}_2\text{NCH}_2\text{CH}(\text{X})\text{CH}_2\text{P}(\text{O})(\text{OH})\text{CF}_2\text{H}$ ($\text{X}=\text{H}, \text{OH}$) were also studied, but these were less potent agonists in a GABA_B binding assay than the corresponding non-fluorinated methyl phosphinate by a factor of ~ 3 – 5 .⁴ Phosphonate $\text{H}_2\text{N}(\text{CH}_2)_3\text{P}(\text{O})(\text{OH})_2$ behaves instead as an antagonist.⁴ The deprotection of the acetal followed by functionalization was also reported in this work (Scheme 1). A few years ago, we reported a general alkylation of *H*-phosphinates, and the preparation of a few α,α -difluoromethylphosphinates.⁵ Herein, we report a study of the alkylation of these and other precursors, which expands upon the Hall precedent.⁴

Scheme 1. Hall's synthesis and elaboration of an α,α -difluorophosphinate.⁴

2. Results and discussion

2.1. Synthesis of difluoromethylphosphinate $\text{RP}(\text{O})(\text{OEt})\text{CF}_2\text{H}$ precursors

Three precursors **1**–**3** were synthesized previously (Eq. 2).⁵ A fourth compound **4** was synthesized similarly from $(\text{EtO})_2\text{CHP}(\text{O})$

(OEt)H. We have been referring to (EtO)₂CRP(O)(OEt)H (R=H, Me) as the ‘Ciba-Geigy reagents’, after their development in that company. As will be discussed below, significant differences exist between compounds **3** and **4**.

The alkylation of *H*-phosphinate esters with lithium hexamethyldisilazide (LiHMDS)⁵ and F₂CHCl (R-22) and mild deoxygenation gives good yields of products **1–4** (71–78%). As we have reported previously, moderate deoxygenation is necessary to achieve good yields of product (this is because the P(III) anion is easily oxidized).^{5,6}

2.2. Functionalization of the difluoromethylphosphinates

Although the P(O)CF₂H group is acidic, electrophilicity of the phosphorus atom is also increased so that P-substitution is an expected competitive pathway. Table 1 shows the outcome of the deprotonation–alkylation process with compound **3** (and methyl iodide as electrophile) as a function of the base employed. *t*-BuLi gives the best results because it is a strong base and less nucleophilic than other butyllithium reagents.

Table 1
Role of the base in the alkylation of **3** with CH₃I

Entry	Base (equiv)	Conditions ^a	Crude NMR yield, ³¹ P and ¹⁹ F (%)	Isolated yield (%)
1	LDA (1.0)	Deoxygenated	20	—
2	LiHMDS (1.0)	Deoxygenated	0	—
3	<i>t</i> -BuLi (1.0)	Deoxygenated	80	—
4a	<i>t</i> -BuLi (1.1)	Deoxygenated	100	91
4b		Without deoxygenation	53	—

^a Unless otherwise noted, all reactions were deoxygenated for 30 min to 1 h prior to adding the base.

The role of electrophile was also investigated (Table 2). Not surprisingly, the less reactive electrophiles gave a lower alkylation yield.

Table 2
Role of the Electrophile in the Alkylation of **3** with *t*-BuLi^a

Entry	Electrophile	Crude NMR, ³¹ P and ¹⁹ F (%)	Isolated yield (%)
1	OctI	100	85
2	OctBr	100	82
4	OctOTs	45	—
3	OctCl	30	—

^a Conditions: (1) deoxygenation, (2) addition of RX at -78°C , 30 min after the base, (3) -78°C to 15°C , 1.5 h, (4) extractive work-up.

2.3. Scope of the alkylation

Compound **3** was treated with several electrophiles (Table 3). The yields are moderate to good. When 0.5 equiv of a dielectrophile is employed, the disubstituted product is obtained.

Table 3
Reactions of phosphinate **3** with some electrophiles

Entry	Base (1.1 equiv)	Electrophile	Isolated yield (%)
1	<i>t</i> -BuLi	Br—CH ₂ —CH ₂ —Br	69 ^a
2	<i>t</i> -BuLi	Br—CH ₂ —CH ₂ —CH ₂ —Br	62 ^a
3	<i>t</i> -BuLi	Br—CH ₂ —CH ₂ —CH ₂ —CH ₂ —Br	65
4	<i>t</i> -BuLi	Cl—CH ₂ —O—Ph	70
5	<i>t</i> -BuLi	Geranyl bromide	52

^a Disubstitution.

Alkylation with a carbohydrate-derived iodide also gave satisfactory results but the product was obtained as the fully hydrolyzed *H*-phosphinic acid (Eq. 3). It is interesting to note that **3** was successful in this reaction, but **4** was not, under otherwise identical conditions. In fact, the reactions of compound **4** are typically very different from that of **3**. Table 4 summarizes the results with methyl iodide and **4** (compare with Table 1). It is expected that the electron-donating methyl substituent in compound **3** will somewhat deactivate the phosphorus atom toward nucleophilic attack. However, the subtle electronic effects translate into significant differences when compared to compound **4**.

Table 4
Role of the base in the alkylation of **4** with CH₃I

Entry	Base (1.1 equiv)	Conditions ^a	Crude NMR yield, ³¹ P and ¹⁹ F (%)	Isolated yield (%)
1	LDA	Deoxygenated	100	62
2	BuLi	Deoxygenated	Some addition to P	—
3	<i>t</i> -BuLi	Deoxygenated	Addition to P major	—

^a All reactions were deoxygenated for 30 min to 1 h prior to adding the base.

Compounds RP(O)(OEt)CF₂R' are hydrolyzed very easily during chromatography on silica gel, even in the presence of some base (like Et₃N) in the eluent. This is not surprising due to the increased electrophilicity of the phosphorus atom with the powerful electron-withdrawing CF₂H group. Thus, products are often isolated and/or characterized as the corresponding *H*-phosphinic esters or acids. *H*-Phosphinate esters RP(O)(OEt)H are typically hydrolyzed rather easily, and the difluoro-substituted compounds RCF₂P(O)(OEt)H are even more prone to further hydrolysis to the corresponding *H*-phosphinic acids RCF₂P(O)(OH)H.

2.4. Alkylation of **2**

Alkylation of compound **2** resulted in an unexpected chain functionalization, as opposed to the difluoromethyl deprotonation/alkylation (Eq. 4).
