# Ceric ammonium nitrate (CAN) catalyzed synthesis of N-substituted decahydroacridine-1,8-diones in PEG

protocol economically and potentially viable.

#### Keywords: Homogeneous catalysis Polyethylene glycol Ceric ammonium nitrate N-Substituted decahydroacridine-1,8-dione Solvent effects

#### 1. Introduction

Substituted acridines have been used as antimalarials<sup>1</sup> for many years guite successfully and several of them have exhibited excellent results in chemotherapy of cancer.<sup>2</sup> These derivatives are frequently used in the industry, especially for the production of dyes.<sup>3</sup> Besides these properties, analogues of acridine have also been shown to have very long lasting efficiencies and have interesting electrochemical behavior<sup>4</sup> of heterocyclic compounds and in the interaction with DNA.<sup>5</sup> In view of the above-mentioned significance, the synthesis of this class of compounds under mild reaction conditions is of importance. Some methods are available in the literature for the synthesis of these acridine compounds from aldehydes, dimedone, and different anilines or ammonium acetate via traditional heating in organic solvents,<sup>6</sup> in water catalyzed by TE-BAC (benzyl tri ethyl ammonium chloride),<sup>7</sup> under microwave irradiation<sup>8</sup> and using ionic liquids.<sup>9</sup> 9,10-Diarylacridine-1,8-diones could also be prepared using *p*-dodecylbenzenesulfonic acid (DBSA) in water.<sup>10</sup> However it should be noted that only *p*-toluidine was selected as a substrate.<sup>10</sup> The other substituted anilines either did not react or gave low yields, especially the anilines containing electron-withdrawing groups. Furthermore most of these methodologies do not meet the requirement of green chemistry as most of these reactions tend to use expensive reagents which are difficult to recover and recycle in volatile organic solvents

which are a threat to the environment due to their pyrophoric nature, volatility, and poor recovery. Ionic liquids which have been used for the synthesis of such compounds<sup>11</sup> require tedious preparation and their environmental safety is still debatable.

Polyethylene glycol (PEG) was found to be an inexpensive non-toxic and effective medium for the one-

pot synthesis of N-substituted decahydroacridine-1,8-diones in the presence of ceric ammonium nitrate

(CAN) as the catalyst in high yields. Also, the solvent system can be recovered and reused; making this

Development of a synthetic protocol that is devoid of the abovementioned problems and yet nature friendly, simple, efficient, and cost effective remains an ever challenging objective.

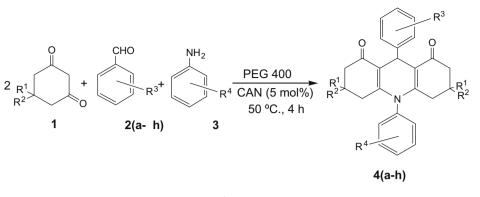

Recently, polyethylene glycol (PEG) is found to be an interesting solvent system.<sup>12</sup> It is a non-toxic, inexpensive, non-ionic liquid solvent of low volatility. PEG and its monomethyl ethers are inexpensive, thermally stable, recoverable, and non-toxic media for phase transfer catalysts.<sup>13,14</sup> PEG is a biologically acceptable polymer which has been used extensively in drug delivery and in bioconjugates as tools for diagnostics. It is being extensively used in organic substrates.<sup>13,14</sup>

Ceric(IV) ammonium nitrate has emerged as an important reagent for the construction of carbon–carbon and carbon–heteroatom bonds.<sup>15</sup> In addition, many advantages such as excellent solubility in water, cost-effectiveness, eco-friendly nature, easy handling, high reactivity, and easy work-up procedures make CAN a potent catalyst in organic synthesis. Besides, CAN is able to catalyze various organic transformations not only based on its electron transfer capacity but also with its Lewis acidic property.<sup>16</sup>

The environmentally benign nature of PEG and the versatility of CAN encouraged us to couple them together and study their utility in the synthesis of N-substituted decahydroacridine-1,8-diones. This is a paradigm shift in the formation of N-substituted decahydroacridine-1,8-diones, both in the context of green chemistry and

the ease, generality, and simplicity of the procedure. Waste generation and side products are largely avoided, and the products can be formed in high yield and purity.

In continuation of our studies in developing cheap and environmentally benign methodologies for organic synthesis,<sup>17</sup> we reveal herein report for the first time the synthesis of N-substituted decahydroacridine-1,8-diones using PEG-400 as a solvent and employing CAN as the catalyst (Scheme 1).

#### 2. Results and discussion

In the initial studies the reaction between cyclohexadione (2 mmol), benzaldehyde (1 mmol), and aniline (1 mmol) was performed in traditional organic solvent (EtOH, Fig. 1). The reaction mixture was stirred for 18 h at 50 °C to obtain 60% of N-substituted decahydroacridine-1,8-dione **4a**, whereas the same reaction in the presence of PEG-400 as an environmentally friendly medium provided 91% of **4a** (Fig. 1) in only 8 h. Various solvents were tried for the same reaction and the results are summarized in Figure 1. PEGs were found to be the best media for this reaction.

To further improve the yield and to optimize the reaction conditions, the same reaction was carried out in the presence of 2 mol % of CAN under similar conditions. A tremendous improvement was observed and the yield of **4a** was increased up to 95% after stirring the mixture for only 6 h. With this optimistic result in hand, we further investigated the best reaction conditions by

**Figure 1.** Synthesis of N-substituted decahydroacridine-1,8-diones in various solvents. Reaction conditions: cyclohexadione (2 mmol), benzaldehyde (1 mmol), aniline (1 mmol); temperature 50 °C. Isolated and unoptimized yields.

using different amounts of CAN. An increase in the quantity of CAN from 2 to 5 mol % not only decreased the reaction time from 6 to 4 h but also increased the product yield from 95% to 98%. This showed that the catalyst concentration plays a major role in the optimization of the product yield. The use of 10 mol % of CAN decreased the yield of the product to 67%. A possible explanation for the low product yield is that the starting material or the product may have been destroyed during the reaction when excess amount (10 mol %) of CAN was used in the reaction and thus 5 mol % CAN is the suitable choice for the optimum yield of N-substituted decahydroacridine-1,8-diones (Table 1).

The effect of temperature on reaction rate as well as on yields of products was also investigated. Faster reactions occurred on increasing the temperature but the product yield decreased at high temperature because one of the reactants oxidizes at high temperature in the presence of CAN (Table 1).
