Abstract

Impact of Coulomb force on Fe₃O₄- Ethylene glycol nanofluid convective heat transfer is examined. The positive electrode is considered as moving wall. Control Volume based Finite Element Method is selected to obtain the outputs which are the roles of Reynolds number (Re), nanofluid volume fraction and supplied voltage ($\Delta\phi$). EFD viscosity of nanofluid according to experimental data is taken into account. Results reveal that electric field boosts the convection mode so heat transfer rate augments by augmenting Coulomb force. Isotherms become denser near the lid wall with augment of Re and $\Delta\phi$. Using electric field is more useful for lower Reynolds number.

Keywords: EHD; Nanofluid; Forced convection; EFD viscosity; Joule heating; CVFEM.
