### A B S T R A C T

Biogenic methods are considered to be a safer alternative to usual physical and chemical methods of nanosynthesis 19 due to their environment friendly nature and cost effectiveness. One major shortcoming of biological methods is 20 their characteristically slow nature. In this study, we report a novel microwave-assisted green method for the 21 rapid synthesis of silver nanoparticles. We synthesized silver nanoparticles by microwave irradiation using the 22 leaf extract of *Biophytum sensitivum* as both the reducing and stabilizing agent. The nanoparticles are characterized 23 by UV–vis, FTIR, XRD and HR-TEM studies. The FTIR spectrum provides sufficient evidences for the involvement of 24 phytochemicals in stabilizing the nanoparticles. The XRD and HR-TEM studies clearly demonstrate the crystalline 25 nature of the nanoparticles. From the TEM images, the silver nanoparticles are found to be almost spherical with 26 an average diameter of 19.06 nm. The synthesized silver nanoparticles have been successfully applied as a catalyst 27 in the degradation of methyl orange and methylene blue by NaBH<sub>4</sub>. 28

### 34 1. Introduction

35 Dye effluents from paper, plastic, food, textile and pharmaceutical 36 industries are now a major threat to the environment due to the substan- 37 tial pollution problems caused by them. The release of these coloured 38 materials into the water bodies causes eutrophication, reduces the reoxy- 39 genation capacity and makes severe damage to the aquatic organisms by 40 hindering the infiltration of sunlight [1,2]. In addition, many of these dyes 41 are mutagenic and carcinogenic and hence cause substantial injury to 42 human life [3,4]. Therefore it is necessary to remove these dyes from 43 our water resources. Conventional water treatment techniques include 44 adsorption, ultrafiltration, biodegradation, chemical, photochemical and 45 electrochemical methods [5–9]. Due to the chemical stability, the dye 46 pollutants are usually resistant to devastation by physicochemical 47 methods. Even though biodegradation methods are cost effective, they 48 are inherently slow and are not effective for dye degradation as these 49 are toxic to microorganisms [10,11]. In recent years, nanocatalysis has 50 emerged as an alternative to conventional water treatment methods. 51 The finite size, large surface area to volume ratio and size dependent reac- 52 tivity have made metal nanoparticles an efficient catalyst [12]. Nowadays 53 nanocatalysts are widely used for the effective removal of dye contami- 54 nants [13–16].

Among metal nanoparticles, silver nanoparticles (AgNPs) still seems 55 to be fascinating due to their excellent optical and electronic properties 56 as well as their wide applications in various fields such as catalysis, op- 57 tics, biomedical, pharmaceutical and sensor technology. Several syn- 58 thetic methodologies are now available for the synthesis of nanoscale 59 silver such as chemical [17], photochemical [18], electrochemical [19], 60 microemulsion [20], and microwave [21]. Most of these methods in- 61 volve the use of toxic chemicals and severe reaction conditions which 62 lead to chemical toxicity and environmental pollution. The negative im- 63 pacts of chemical methods and the increasing focus on green chemistry 64 have augmented the importance of biological method of nanosynthesis. 65 The biomediated methods are considered to be a feasible alternative to 66 physical and chemical methods because of its ease, eco-friendly nature 67 and cost effectiveness. Several groups have reported the synthesis of 68 silver nanoparticles using plant extracts as both the reducing and 69 capping agent [22–25]. One drawback of biological methods is that 70 they are slow compared to chemical methods. This limitation can be 71 overcome by incorporating microwave chemistry with biomediated 72 methods. Microwave-assisted biosynthesis using plant extracts as 73 both reducing and stabilizing agent is a viable method for the rapid 74 and easy synthesis of silver nanoparticles. Microwave irradiation causes 75 rapid and uniform heating of the reaction medium and thus pro- 76 vides homogeneous nucleation and growth conditions resulting in 77 monodispersed nanoparticles in short reaction time [26]. In our recent 78 work, we have reported the microwave-assisted biosynthesis of silver 79 nanoparticles using the leaf extract of *Aerva lanata* [27]. 80

In this article, we present a novel microwave-assisted method for the synthesis of silver nanoparticles using the aqueous leaf extract of the plant *Biophytum sensitivum* as both the reducing and capping agent. This is a simple, one pot, and green method for the quick and facile synthesis of silver nanoparticles. *B. sensitivum* is a small annual herb belonging to the family Oxalidaceae. The flowers of the plant are significant for its medicinal, cultural and traditional values. *B. sensitivum* has several medicinal properties and the plant parts are used in the treatment of asthma, inflammatory diseases and diabetes. The biological activity of the plant shows hypoglycemic, immunomodulatory, chemoprotective, hypocholesterolemic, antiinflammatory, antitumor, and antibacterial activity [28,29]. The phytochemical analysis of the plant showed the presence of amentoflavone, 3',8"-biapigenin, proanthocyanidins and phenolic compounds [30]. The catalytic activity of the silver nanoparticles synthesized using *B. sensitivum* leaf extract (AgNP-biophytum) was investigated by using them in the degradation reactions of methyl orange and methylene blue by NaBH<sub>4</sub>.

## 2. Materials and methods

### 2.1. Materials

Silver nitrate (AgNO<sub>3</sub>), methyl orange, methylene blue and sodium borohydride (NaBH<sub>4</sub>) of analytical grade were purchased from Merck (India) and used as such without further purification. All aqueous solutions were prepared using double distilled water.

### 2.2. Methods

#### 2.2.1. Preparation of *B. sensitivum* leaf extract

Green fresh leaves of *B. sensitivum* were collected and authenticated. Twenty five grams of the leaves were washed thoroughly with distilled water to remove any dirt particles adhering to it and then it was chopped into small pieces. These were taken in a round bottom flask fitted with water condenser and boiled for 10 min with 100 mL of double distilled water. It was cooled and filtered through Whatman No. 1 filter paper. The extract thus obtained was stored at 4 °C for further use.

#### 2.2.2. Biosynthesis of silver nanoparticles

In microwave-assisted synthesis, 90 mL of 1 mM silver nitrate solution was taken in a 250 mL beaker. To this, 10 mL *B. sensitivum* leaf extract was added and stirred well. This was placed in a domestic microwave oven (Sharp R-219T (W)) operating at a power of 800 W and frequency 2450 MHz and was subjected to microwave irradiation for 3 min. The formation of silver nanoparticles (AgNP-biophytum) was monitored using a UV-vis spectrometer by analysing the reaction mixture after 0, 1, 2 and 3 min of microwave irradiation in the range of 250–700 nm. The silver nanoparticle solution was then centrifuged at a speed of 10,000 rpm for 10 min. The supernatant was decanted and

the nanoparticles were redispersed in distilled water. The above process was repeated thrice in order to remove impurities and any unused biomaterials. The purified sample was freeze dried to get dry particles. The nanosynthesis was also carried out at room temperature without microwave-assistance in order to learn the effect of microwave heating on the rate of formation of nanoparticles. For that, 10 mL of *B. sensitivum* extract was added to 90 mL of 1 mM aqueous solution of silver nitrate and the reaction mixture was kept at room temperature for 24 h. The reaction mixture was subjected to UV-vis spectroscopic analysis at regular intervals in order to examine the formation of AgNP-biophytum.

#### 2.2.3. Catalytic degradation of methyl orange

The catalytic degradation of methyl orange by NaBH<sub>4</sub> was studied as follows. To 2 mL of aqueous methyl orange solution ( $0.01 \times 10^{-2}$  M) was taken in a quartz cell of 1 cm path length and 0.5 mL freshly prepared NaBH<sub>4</sub> solution (0.06 M) was added. Followed by this, 0.5 mL of AgNP-biophytum solution of a definite concentration was added to start the reaction. The variation in the concentration of methyl orange with time was monitored using UV-vis spectrophotometry by following the change in the absorbance of the peak at 464 nm. The absorption spectra were recorded at 1 min intervals in the range of 200–600 nm at an ambient temperature.

#### 2.2.4. Catalytic degradation of methylene blue

To study the catalytic degradation of methylene blue by NaBH<sub>4</sub>, 0.5 mL of newly prepared NaBH<sub>4</sub> solution (0.06 M) was added to 2 mL of aqueous methylene blue solution ( $0.08 \times 10^{-3}$  M) in a quartz cuvette. Then 0.5 mL nanocatalyst solution of a certain concentration was added and the progress of the reaction was followed spectrophotometrically by monitoring the change in the intensity of the peak at 664 nm. The absorption spectra were recorded at 1 min intervals in the range of 400–800 nm at an ambient temperature.

#### 2.2.5. Characterization

UV-vis spectral analysis was carried out using a Shimadzu UV-2450 spectrophotometer. FTIR spectrum was recorded on a Perkin Elmer-400 spectrometer with ATR attachment. XRD measurement was made on a PANalytic X'PERT-PRO X-ray spectrometer. The XRD sample was prepared by drop coating the nanoparticle solution on a glass slide followed by drying under ambient condition. High resolution-transmission electron microscopic (HR-TEM) images were taken using a JEOL JEM-2100 microscope.

## 3. Results and discussion

### 3.1. UV-vis spectroscopic studies

UV-vis spectroscopy is a valuable tool to establish the formation and stability of metal nanoparticles because nanoparticle solution shows
