**Abstract**

Phase equilibria in the Fe-Ce-C system at 1100°C were studied using X-ray diffraction, SEM and electron probe microanalysis. An isothermal section at this temperature was constructed covering the whole concentration range. The stability of the ternary compound  $\tau_1$  at 1100°C, identified previously, was confirmed and its composition determined as 23Fe-29Ce-48C according our data. It is also confirmed that the ternary compound  $\tau_1$  does not have a homogeneity range. The liquid phase is stable at 1100°C in the Fe-Ce-C system. The isothermal section is characterized by five three-phase regions:  $(\gamma\text{Fe}) + (\text{C}) + (\alpha\text{CeC}_2)$ ,  $(\gamma\text{Fe}) + \tau_1 + (\alpha\text{CeC}_2)$ ,  $(\gamma\text{Fe}) + \tau_1 + (\text{Ce}_2\text{C}_3)$ ,  $(\alpha\text{CeC}_2) + \tau_1 + (\text{Ce}_2\text{C}_3)$  and  $\text{L} + (\gamma\text{Fe}) + (\text{Ce}_2\text{C}_3)$  plus the corresponding two-phase regions.

**Keywords:** Phase diagram, ternary compound, isothermal section, Fe-Ce-C, rare earth metal, phase equilibria, lanthanides
