## ABSTRACT

The different atomic ratios of FeCo alloys with various morphologies have been prepared through a simple liquid-thermal reduction method. It is found that the atomic ratio of ferrum and cobalt has great influence on the formation of FeCo alloys. Via adjusting Fe/Co atomic ratio (3:7, 5:5, 7:3), the surface of alloy becomes smooth gradually from distinct cone structure, and the saturation of alloys have been improved with the increase of Fe proportion. The impedance matching is also related tightly with atomic ratio and the best condition can be achieved by Fe<sub>7</sub>Co<sub>3</sub> with lower dielectric constant and higher permeability. It is delighted to find that the optimal reflection loss (RL) value of Fe<sub>7</sub>Co<sub>3</sub> can reach −53.6 dB at 14.3 GHz with a thin thickness of 1.55 mm and the RL values less than −10 dB can be gained from 11.2 to 18 GHz, which covering the whole Ku-band. The excellent performance derived from strong magnetic loss and well dielectric loss guarantees it as an ideal high-frequency microwave absorbent.

## 1. Introduction

Recently, serious electromagnetic pollution come from electronic devices, wireless communication tools and radar systems bring great threatens to human health and commercial equipment. In order to solve these problems, the high-efficiency microwave absorbent with “strong absorption, broad bandwidth, light weight and thin coating thickness” is greatly demanded [1–4]. So far, many composites with dielectric loss and magnetic loss were applied in the area of microwave absorption [5,6]. However, the complicated synthesis process restricts the development of these materials. As we all know, the impedance matching is important for the absorber, so the lower complex dielectric constant and higher complex permeability is needed [7]. Therefore, as typical soft magnetic material, metal or metal alloy exhibits many merits such as simple preparation process, strong magnetic loss, high saturation magnetization and high Curie temperature [8]. For instance, the flaky carbonyl particles were fabricated by a heating-balling method, which showed broad bandwidth in the 8–18 GHz

below −8 dB [9]. Liu et al. reported the different morphologies of the Co<sub>20</sub>Ni<sub>80</sub> nanoparticles which exhibited distinct microwave absorption properties. It was found that the reflection loss value of urchin-like Co<sub>20</sub>Ni<sub>80</sub> can reach as high as −33.5 dB at 3 GHz and the absorption bandwidth is about 5.5 GHz for the flower-like morphology [10].

According to the impedance matching equation express as follows: [11,12].

$$Z = Z_1/Z_0 \quad (1)$$

$$Z_1 = (\mu_r/\epsilon_r)^{1/2}Z_0 \quad (2)$$

where  $Z_0$  represents the impedance of the free space,  $Z_1$  means the impedance value of the absorption material,  $\mu_r$  is complex permeability values and  $\epsilon_r$  is complex permittivity values. The best way to achieve impedance matching is to make the relative complex permittivity  $\epsilon_r$  closer to the relative complex permeability  $\mu_r$ . Due to its high permeability, FeCo alloy is suitable as microwave absorbers if dielectric constant can be reduced [13]. Our group fabricated the hexagonal-cone like Fe<sub>50</sub>Co<sub>50</sub> alloy which possess decent microwave absorption performance with RL values of −22 dB and frequency bandwidth of 7.1 GHz [14]. Nevertheless,

the atomic ratio of FeCo alloys was scarcely reported, which has significant influence on the microwave absorption. On the other hand, the high value of  $M_s$  can lead to high value of  $\mu_0 ((\mu_0 - 1)f_0 = 1/$

$3\pi\gamma Ms$ ), but high value of  $\epsilon_r$  for FeCo alloys give rise to the most microwave be reflected, so the microwave will not be attenuated effectively.

In this study, we introduce the FeCo alloys with different atomic ratio and high saturation magnetization synthesized by a simple liquid-thermal reduction process. It was found that the atomic ratio of Fe/Co has great influence on the dielectric constant and morphology. So the well impedance matching, strong microwave absorption and wide frequency range can be attained by adjusting atomic ratio of Fe/Co. Generally, the increase of Fe proportion in FeCo alloys is a valid way to bring down dielectric constant and improve impedance matching which makes FeCo alloy become an ideal microwave absorber.

## 2. Experimental section

### 2.1. Synthesis of FeCo alloys with different atomic ratios

All of the reagents used in this experiment are analytical pure without further purification. A simple liquid-thermal reduction method as previous report with a little modified was used to prepare alloys [15]. Typically, a certain ratio amount of  $\text{FeCl}_2$  and  $\text{CoCl}_2$ , totally 40 mmol, was dispersed uniformly in 150 mL deionized water with adding 0.3 mol citrate trisodium,
