13 **Abstract**

14 The following article conducts a meta-analysis to systematically investigate why Representative Concentration
15 Pathways (RCPs) in the Fifth IPCC Assessment are illustrated with energy system reference cases dominated by coal.
16 These scenarios of 21st-century climate change span many decades, requiring a consideration of potential
17 developments in future society, technology, and energy systems. To understand possibilities for energy resources in
18 this context, the research community draws from Rogner (1997) which proposes a theory of learning-by-extracting
19 (LBE). The LBE hypothesis conceptualizes total geologic occurrences of oil, gas, and coal with a learning model of
20 productivity that has yet to be empirically assessed.

21 This paper finds climate change scenarios anticipate a transition toward coal because of systematic errors in fossil
22 production outlooks based on total geologic assessments like the LBE model. Such blind spots have distorted
23 uncertainty ranges for long-run primary energy since the 1970s and continue to influence the levels of future climate
24 change selected for the SSP-RCP scenario framework. Accounting for this bias indicates RCP8.5 and other ‘business-
25 as-usual scenarios’ consistent with high CO₂ forcing from vast future coal combustion are exceptionally unlikely.
26 Therefore, SSP5-RCP8.5 should not be a priority for future scientific research or a benchmark for policy studies.
