8     **Abstract**

9             Biomass-steam gasification is an efficient unitization technology of biomass to  
10    produce gas fuel for a combined cooling, heating and power (CCHP) system. The aim  
11    of this paper is to modify the exergoeconomic method and analyze the cost allocations  
12    of multi-products from CCHP system. Firstly, two integrated CCHP schemes with  
13    biomass-steam gasification are designed. The difference lies in the gasification  
14    endothermic process driven by electricity and thermal energy from the product gas,  
15    respectively. The thermodynamic models are presented and validated. Then, a  
16    modified exergoeconomic method based on energy level is proposed to accord with  
17    the principle of high quality and high price. Finally, a case study is presented to  
18    analyze the thermodynamic performances of two CCHP schemes and the production  
19    cost allocations including electricity, chilled water for cooling (hot water for heating)  
20    and domestic hot water in different operation modes. Compared with the previous  
21    exergoeconomic method, the unit exergy cost of electricity with higher energy level  
22    increases 0.09 Yuan/kWh while the cost of other products with lower energy level  
23    decrease. The results show that the modified exergoeconomic method is more  
24    reasonable and efficient.
