This is a PDF file of an unedited manuscript that has been accepted for publication. As a service to our customers we are providing this early version of the manuscript. The manuscript will undergo copyediting, typesetting, and review of the resulting proof before it is published in its final form. Please note that during the production process errors may be discovered which could affect the content, and all legal disclaimers that apply to the journal pertain.

**Highlights**

- Combined Cassini data result in hemispheric composite spectra of Saturn's moons.
- Ultraviolet and visible spectral trends are compared with exogenic processes.
- Results are consistent with E ring organics being responsible for coloring the moons.
- Electrons in the tens of keV range may be particularly effective at darkening and reddening.
