**Background:** Coronary artery involvement is not a rare presentation of Takayasu arteritis (TA) and the treatment is challenging. The optimal methods of revascularization, and prognosis of treatment have not been established.

**Objectives:** To assess the long-term outcomes of percutaneous coronary intervention (PCI) and coronary artery bypass grafting (CABG) in TA patients.

**Methods:** Patients with coronary artery involved in TA who underwent either PCI or CABG were identified between February 2003 and December 2015. The primary outcome was long-term all-cause mortality. Secondary outcomes were myocardial infarction (MI), stroke, and repeat revascularization.
