10 **ABSTRACT**

11 The main predispositions that constrain food preferences comprise the tendency to prefer sweet
12 foods and to reject bitter foods, as well as to favor more familiar foods and rejecting novel foods.
13 Much evidence indicates that preference for sweet taste is inborn and universally present in
14 neonates and that it decreases during adult life. However, there are no clear findings regarding age-
15 related changes during adulthood and in the elderly. In the current study we aimed to assess, in a
16 large sample of healthy participants, ratings of food images by taking into account valence, arousal
17 and familiarity judgments. Our results demonstrate a clear pattern of sweet taste valence and arousal
18 attribution across the different age groups, that seems to decline up to early middle age and to
19 increase thereafter, so that it is again present in elderly people. Such result could be accounted for
20 by the fact that sweet foods might constitute a non-poisonous energy source and/or an immediate
21 calorie supply for individuals with impaired energetic metabolism, providing new insights into the
22 field of human food preferences. Moreover, gender and weight status differences were observed as
23 regards preferences for specific food categories.
