11 Abstract

12 Using joint permutation entropy we address the issue of minimizing the cost of monitoring, while
13 minimizing redundancy of the information content, of daily streamflow data recorded during the period
14 1989–2016 at twelve gauging stations on Brazos River, Texas, USA. While the conventional entropy
15 measures take into account only the probability of occurrence of a given set of events, permutation
16 entropy also takes into account local ordering of the sequential values, thus enriching the analysis. We
17 find that the best cost efficiency is achieved by performing weekly measurements, in comparison with
18 which daily measurements exhibit information redundancy, and monthly measurements imply information
19 loss. We also find that the cumulative information redundancy of the twelve considered stations is over
20 10% for the observed period, and that the number of monitoring stations can be reduced by half bringing
21 the cumulative redundancy level to less than 1%.
