Representation zeta function

ABSTRACT

We give an explicit construction of all complex continuous irreducible characters of the group $SL_1(D)$, where D is a division algebra of prime degree ℓ over a local field of odd residual characteristic different from ℓ . For ℓ odd, we show that all such characters of $SL_1(D)$ are induced from linear characters of compact-open subgroups of $SL_1(D)$. We also compute an explicit formula for the representation zeta function of $SL_1(D)$.

1. Introduction

Let K be a local field with ring of integers \mathfrak{o} of odd residual characteristic p , and let D be a central division algebra over K . Let ℓ denote the degree of D , that is $\ell = (\dim_K(D))^{1/2}$. Let L/K be an extension of degree ℓ . The field L embeds in D as a maximal subfield and hence there exists an embedding of D into the full matrix algebra $\mathbf{M}_\ell(L)$. The restriction of the determinant map to the image of D in $\mathbf{M}_\ell(L)$ gives rise to the reduced norm map, denoted by Nrd . This definition is independent of the choice of extension L/K and of the embedding of L into D (see [14]). The valuation map $\mathrm{val}_K : K \rightarrow \mathbb{Z} \cup \{\infty\}$ extends uniquely to D via the formula

$$\mathrm{val}_D(x) = \frac{1}{\ell} \mathrm{val}_K(\mathrm{Nrd}(x)) \quad (x \in D). \quad (1.a)$$

Let $\mathrm{SL}_1(D)$ be the subgroup of elements of reduced norm 1 in D^\times . In this article we focus on the group $\mathrm{SL}_1(D)$ and give an explicit construction of all complex continuous irreducible characters of $\mathrm{SL}_1(D)$, under the assumption that ℓ is a prime number different from p . This construction enables us to determine the number of such irreducible characters of $\mathrm{SL}_1(D)$ of any given dimension. In particular, we obtain a formula for the representation zeta function of $\mathrm{SL}_1(D)$.

Given a topological group Γ we write $\mathrm{Irr}(\Gamma)$ to denote the set of complex continuous irreducible characters of Γ . The representation zeta function of Γ is defined by the Dirichlet generating function

$$\zeta_\Gamma(s) := \sum_{\chi \in \mathrm{Irr}(\Gamma)} \chi(1)^{-s} \quad (s \in \mathbb{C}). \quad (1.b)$$

The abscissa of convergence of $\zeta_\Gamma(s)$ is the infimum of all $\alpha \in \mathbb{R}$ such that the series in (1.b) converges on the complex right half-plane $\{s \in \mathbb{C} \mid \mathrm{Re}(s) > \alpha\}$.

In the case where Γ is a compact p -adic analytic group (for $p > 2$), Jaikin-Zapirain has shown that the representation zeta function of Γ is of the form

$$\zeta_\Gamma(s) = \sum_{i=1}^r n_i^{-s} f_i(p), \quad (1.c)$$
