Abstract

A method for the decomposition of data functions sampled on a finite fragment of triangular lattices is described for the lattice corresponding to the simple Lie group $SU(3)$. The basic tile (fundamental region) of $SU(3)$ is an equilateral triangle. The decomposition matrices refer to lattices that carry data of any density. This main result is summarized in Section 4 Theorem 2.

Keywords: decomposition matrices, discrete Fourier transform, $SU(3)$ group

1. Introduction

The processing of digital data sampled on some fragment F of a lattice is a standard problem of data processing in the 2-dimensional real Euclidean space \mathbb{R}^2 [3, 6]. Typically for two dimensional data, it is common to sample data utilizing a rectangular lattice. However, this is not always the ideal choice in terms of considerations such as sampling density. For example it has been shown that for isotropic fields in \mathbb{R}^2 the hexagonal lattices are useful [5]. Equally common is the need to process a series of pictures on the same fragment of the lattice (e.g. video) [5]. In many cases an important first step to various data processing problems is the decomposition of the data into a finite series of special functions. The maximal number of non-zero terms such a series can have is equal to the number of lattice points in F which carry data.
