ABSTRACT

The cytokine lymphotoxin- α (LT α) is a promising candidate for use in cancer therapy. However, the instability of LT α *in vivo* and the insufficient levels of tumor necrosis factor receptor 1 (TNFR1)-mediated bioactivity of LT α limit its therapeutic potential. Here, we created LT α mutants with increased TNFR1-mediated bioactivity by using a phage display technique. We constructed a phage library displaying lysine-deficient structural variants of LT α with randomized amino acid residues. After affinity panning, we screened three clones of lysine-deficient LT α mutant, and identified a LT α mutant with TNFR1-mediated bioactivity that was 32 times that of the wild-type LT α (wtLT α). When compared with wtLT α , the selected clone showed augmented affinity to TNFR1 due to slow dissociation rather than rapid association. In contrast, the mutant showed only 4 times the TNFR2-mediated activity of wtLT α . In addition, the LT α mutant strongly and rapidly activated caspases that induce TNFR1-mediated cell death, whereas the mutant and wtLT α activated nuclear factor-kappa B to a similar extent. Our data suggest that the kinetics of LT α binding to TNFR1 play an important role in signal transduction patterns, and a TNFR1-selective LT α mutant with augmented bioactivity would be a superior candidate for cancer therapy.

1. Introduction

Lymphotoxin-alpha (LT α) is a tumor necrosis factor (TNF) superfamily cytokine with tumor-cell-specific cytotoxic activity and immune-activating activity. LT α induces the expression of che-

mokines and adhesion molecules in endothelial cells, and plays a key role in lymph node neogenesis [1–3]. Schrama et al. [4,5] showed that systemic administration of LT α to a tumor-bearing mouse leads to the construction of ectopic lymphoid tissue within the tumor and the strong induction of tumor immunity in that lymphoid tissue, suggesting that the underlying mechanism of this cytokine's anti-tumor activity may be effective. Therefore, LT α has long been considered to be a promising candidate for an anti-cancer agent. However, the clinical use of LT α has been limited because of the protein's *in vivo* instability and proinflammatory side effects.

One of the most common ways to improve the therapeutic effects of proteins is to conjugate them with polyethylene glycol (PEG) in a process called PEGylation, or to conjugate them with other water-soluble polymers [6]. Because of the steric hindrance caused by the PEG molecule, PEGylation can prolong the plasma half-life of molecules and alter the tissue distribution of the conjugates compared with those of the native form. PEGylation of proteins is mostly nonspecific because it targets all of the lysine residues in the protein, some of which may be in or near an active site. As a result, PEGylation significantly reduces the specific

activity of the proteins involved. Our group previously developed a novel strategy for site-specific mono-PEGylation of lysine-deficient mutants to overcome these limitations of PEGylation [7,8]. We demonstrated that site-specific PEGylation of a lysine-deficient mutant of LT α retained higher bioactivity compared with random PEGylation of wild-type LT α (wtLT α) [9]. This finding suggests that site-specific PEGylation of a lysine-deficient mutant of LT α might be a useful way to overcome the problems in the clinical use of LT α outlined above.

LT α binds to three receptor subtypes—TNF receptor 1 (TNFR1), TNFR2, and herpes virus entry mediator (HVEM)—to exert various biological functions. TNFR1 induces an anti-tumor effect and Peyer's patch development, whereas TNFR2 is essential for immune responses against bacteria and viruses [1]. Human LT α and TNF that bind to murine TNFR1, but not to murine TNFR2, are not lethal in healthy mice except at extremely high doses, suggesting that LT α and TNF α exhibit their lethal side effects via TNFR2 [10,11]. Therefore, LT α as a cancer immunotherapeutic agent, a LT α mutant with selectively increased TNFR1-mediated bioactivity is needed. Previously, we successfully created a TNFR1-selective LT α mutant whose bioactivity via TNFR1 was several times that of wtLT α , and whose bioactivity via TNFR2 was 2.5% that of wtLT α [12]. However, to enhance therapeutic efficacy and suppress the side effect of LT α , it is necessary to create a LT α mutant with greatly increased TNFR1-mediated bioactivity and TNFR1-selectivity.

In this study, we attempted to create LT α mutants with selectively increased TNFR1-mediated bioactivity by using a phage display technique. We succeeded in creating a LT α mutant that had a much higher bioactivity via TNFR1 and an augmented affinity to TNFR1 compared with that of wtLT α , and demonstrated that this was due to the slow dissociation rate of the LT α mutant-TNFR1 complex. In addition, we showed that the LT α mutant differed from wtLT α by its ability to strongly and rapidly activate caspases. In contrast, the LT α mutant and wtLT α were similar to each other in their degree of activation of nuclear factor-kappa B (NF κ B). Our findings suggest that this LT α mutant would be a superior candidate for a cancer immunotherapeutic agent.

2. Materials and methods

2.1. Cells

HEp-2 cells, a human carcinoma cell line derived via HeLa contamination, were purchased from the American Type Culture Collection (Manassas, VA), and cultured in RPMI 1640 medium (Wako Pure Chemical Industries, Osaka, Japan) supplemented with 10% fetal bovine serum (FBS), 1 mM sodium pyruvate, 50 μ M 2-mercaptoethanol, and antibiotics. HT29.14S cells, a TNF/LT-sensitive subclone of HT29 human colon adenocarcinoma, were kindly provided by Dr. Carl Ware (La Jolla Institute for Allergy and Immunology, CA) [13]. HT29.14S cells were cultured in Dulbecco's Modified Eagle's Medium (Wako Pure Chemical Industries) supplemented with 10% FBS, 10 mM HEPES, and antibiotics. hTNFR2/mFas-PA cells are preadipocytes derived from TNFR1^{-/-} TNFR2^{-/-} mice expressing a chimeric receptor composed of the extracellular and transmembrane domain of human TNFR2 and the intracellular domain of mouse Fas, which is a member of the TNF receptor superfamily [14]; these cells were cultured in RPMI 1640 medium supplemented with 10% FBS, 5 μ g/mL Blasticidin S HCl (Invitrogen, Carlsbad, CA), and antibiotics. MCF-7 cells were provided from the Institute of Development, Aging and Cancer, Tohoku University, and were cultured in Eagle's Minimum Essential Medium (Wako Pure Chemical Industries) supplemented with 10% FBS, 0.01 mg/mL bovine insulin, and antibiotics.

2.2. Construction of a library of lysine-deficient mutants of LT α

The phagemid vector pY03', which encodes human wtLT α with the C-terminus of wtLT α fused to the N-terminus of the M13 phage g3p, was used as a PCR template for constructing a DNA library of lysine-deficient mutants of LT α . We performed a two-step PCR amplification using oligonucleotides containing the sequence NNS (where N represents A, C, G, or T; and S represents C or G) at Lys19, Lys28, Lys39, Lys84, Lys89, and Lys119 of wtLT α ; the sequence NNS encodes all 20 standard amino acids. The products from the second PCR were digested with *Nco*I and *Pst*I and then ligated into pY03'. The phagemid was electroporated into *Escherichia coli* (*E. coli*) TG1 cells (Stratagene, Cedar Creek, TX), yielding 2×10^6 independent clones. The phage library displaying lysine-deficient LT α molecules was prepared as described previously [12]. Briefly, pY03'-transformed TG1 cells were infected with M13KO7 helper phage (Invitrogen) and cultured for 6 h at 25 °C. The resultant phage particles were precipitated from the culture supernatant by using PEG (MP Biomedicals, Solon, OH) and suspended in NTE (100 mM NaCl, 10 mM Tris, 1 mM EDTA).

2.3. Selection of bioactive LT α mutants

Screening for bioactive LT α mutants was performed as described previously [12]. Briefly, an immunoplate was coated with soluble human TNFR1 (R&D Systems, Minneapolis, MN), and the prepared phage library was allowed to bind to the immobilized TNFR1. After a second round of panning, single colonies were picked and cultured. The resulting phage-containing culture supernatant was used for screening by enzyme-linked immunosorbent assay (ELISA) against human TNFR1.

2.4. Expression and purification of recombinant LT α s

pET15b plasmids (Novagen, Darmstadt, Germany) encoding LT α s were prepared and used to transform *E. coli* BL21(DE3) cells (Stratagene) for the expression of recombinant protein, as described previously [12]. Expression was induced by adding 1 mM isopropyl β -D-1-thiogalactopyranoside and incubating the cells at 37 °C for 6 h in Terrific Broth (Invitrogen Corporation, Carlsbad, CA) containing 0.4% glucose, 1.68 mM MgSO₄, and 100 μ g/mL of ampicillin; all products were accumulated as inclusion bodies. The resultant inclusion bodies were washed, solubilized, reduced, and refolded by the methods previously described [12]. After dialysis against a buffer containing 20 mM Tris-HCl (pH 7.4) and 100 mM urea, active trimeric LT α proteins were purified by using a HiLoad Superdex 200PG column (GE Healthcare, UK) equilibrated with phosphate-buffered saline (pH 7.4) followed by ion-exchange chromatography (SP Sepharose Fast Flow for wtLT α ; Q Sepharose Fast Flow for mutants of LT α); both columns were obtained from GE Healthcare. To create point mutants, we used pET15b-human wtLT α as a template with a KOD-plus mutagenesis kit (Toyobo, Osaka, Japan) according to the manufacturer's instructions. Recombinant point mutants were produced and purified as described earlier; SP Sepharose Fast Flow was used as the ion-exchange column. Protein concentration was measured by using Coomassie Protein Assay Reagent (Thermo Fisher Scientific, Rockford, IL). Sodium dodecyl sulfate-polyacrylamide gel electrophoresis (SDS-PAGE) analysis of LT α s was conducted under reducing conditions, and the proteins in the gels were stained with Coomassie brilliant blue. The electrostatic potential surface was generated by using GRASP software [15]. The electrostatic potential ranged from -7.5 kT to 7.5 kT. The relative accessible surface areas were calculated by using JOY software [16].
