## ABSTRACT

A La<sub>0.6</sub>Sr<sub>0.4</sub>Co<sub>0.2</sub>Fe<sub>0.8</sub>O<sub>3-δ</sub> (LSCF) cathode modified using nanosized TiO<sub>2</sub> was directly prepared on the yttria stabilized zirconia (YSZ) electrolyte in an intermediate temperature solid oxide fuel cell. TiO<sub>2</sub> prevents reaction between LSCF and YSZ, which would have formed a SrZrO<sub>3</sub> phase. The cell with a LSCF-0.25 wt% TiO<sub>2</sub> cathode exhibited a current density that was 1.6 times larger than that with a pure LSCF cathode at 0.7 V and 600 °C. Electrochemical impedance spectra showed the accelerated incorporation of oxygen anions into the YSZ electrolyte with the TiO<sub>2</sub>-modified LSCF cathode. The improvement was attributed to the suppressed formation of a non-conductive SrZrO<sub>3</sub> layer at the cathode/electrolyte interface.

## 1. Introduction

Solid oxide fuel cells (SOFCs) directly convert chemical energy stored in fuels to electrical energy [1]. The traditional SOFC has the components Ni-YSZ (YSZ = yttria stabilized zirconia) anode, YSZ electrolyte, and (La,Sr)MnO<sub>3</sub>-YSZ cathode and operates in the 800–1000 °C range [2,3]. To reduce the operating temperature of SOFCs, La<sub>1-x</sub>Sr<sub>x</sub>Co<sub>y</sub>Fe<sub>1-y</sub>O<sub>3-δ</sub> (LSCF) materials with a high electronic and ionic conductivity (MIEC) and excellent catalytic activity for oxygen reduction are extensively studied as the SOFC cathode [4]. However, unlike (La,Sr)MnO<sub>3</sub> materials, (La,Sr)(Co,Fe)O<sub>3</sub> suffers significant Sr surface segregation and easily reacts with YSZ to form non-conductive phases of SrZrO<sub>3</sub> and/or La<sub>2</sub>Zr<sub>2</sub>O<sub>7</sub> even at 700 °C [5]. This leads

to very large interfacial losses when the LSCF cathode is directly prepared on the YSZ electrolyte. Much effort has been devoted to preventing the formation of the non-conductive phases, such as adding Gd-doped CeO<sub>2</sub> (GDC) as an interlayer to avoid direct contact between the cathode and YSZ electrolyte [6–8] or infiltrating the cathode material (such as La<sub>1-x</sub>Sr<sub>x</sub>Co<sub>y</sub>Fe<sub>1-y</sub>O<sub>3-δ</sub>) into the YSZ scaffold and sintering at low temperature to avoid the unwanted interfacial reaction [9]. However, these methods add to the cost and complexity of the cell fabrication and introduce new interfacial losses between the GDC interlayer and YSZ electrolyte. Therefore, it is useful to develop a new method for the direct application of an LSCF cathode on the ZrO<sub>2</sub>-based (such as YSZ) electrolyte.

The interface between different phases can be changed by

adding a proper modifier. For example,  $\text{Co}_3\text{O}_4$  has been studied as a sintering aid to modify the microstructure of a Co-containing perovskite cathode and the interface of the cathode/electrolyte [10].  $\text{TiO}_2$  has been widely used as a photocatalyst because of its high stability, non-toxicity, and relatively low cost [11,12]. In the field of SOFC glass sealing materials,  $\text{TiO}_2$  has been used to tune the crystallization temperature and microstructure of glass materials, and  $\text{TiO}_2$ -modified  $\text{Bi}_2\text{O}_3$ - $\text{BaO}$ - $\text{SiO}_2$ - $\text{R}_x\text{O}_y$  ( $\text{R} = \text{K}, \text{Ca}$ , etc.) shows a good match of the thermal properties and firm adherence to the electrolyte and connector [13].  $\text{TiO}_2$  has been added to a  $\text{CeO}_2$ -based electrolyte to reduce the sintering temperature and improve the grain boundary conduction [14]. The addition of  $\text{TiO}_2$  into an LSCF can prevent the reaction of LSCF with YSZ by the interaction between LSCF and  $\text{TiO}_2$  and modify the interface of the cathode/electrolyte.

In this study, nanosized  $\text{TiO}_2$  particles were added into an LSCF cathode by an ultrasound-assisted blending process. The  $\text{TiO}_2$ -modified LSCF cathode was directly applied on the YSZ electrolyte. The interaction of the LSCF,  $\text{TiO}_2$ , and YSZ oxides were studied by X-ray diffraction (XRD). The effects of  $\text{TiO}_2$  addition on cell performance were studied by electrochemical analysis and scanning electron microscopy (SEM).

## 2. Experimental

Anode-supported single cells with a thin film YSZ (10  $\mu\text{m}$ ) were fabricated by the tape casting method. The anode-electrolyte bilayer assemblies were sintered at 1295  $^\circ\text{C}$  for 3 h. The homemade  $\text{La}_{0.6}\text{Sr}_{0.4}\text{Co}_{0.2}\text{Fe}_{0.8}\text{O}_{3-\delta}$  (LSCF) powder was synthesized by a citric acid ammonium-assisted Pechini-type method [15] and sintered at 1050  $^\circ\text{C}$  for 3 h. The  $\text{TiO}_2$ -modified LSCF cathode was made by the ultrasound assisted process as follows. Commercial  $\text{TiO}_2$  (Zhenjiang, China) nanoparticles were added into deionized water with a  $\text{TiO}_2$  concentration of 0.25 mol/L. The LSCF powder was blended with various amounts of  $\text{TiO}_2$  nanoparticles using an ultrasonic bath with a frequency of 25 kHz and a nominal power of 600 W for 30 min. The cathode slurry consisting of dried LSCF- $\text{TiO}_2$  composite oxides, organic binders, and solvent was coated on the YSZ electrolyte and sintered at 850  $^\circ\text{C}$  for 2 h. The thickness of the cathode was 35  $\mu\text{m}$ .

The single cells were tested in the homemade electrochemical device. Humidified  $\text{H}_2$  (3%  $\text{H}_2\text{O}$ ) and pure  $\text{O}_2$  flow were supplied as fuel and oxidant, respectively. The current-voltage curves and corresponding power density ( $I$ - $V$ - $P$ ) of single cells were measured using the two-electrode four-wire method at 600–750  $^\circ\text{C}$ . Electrochemical impedance spectra were measured under open circuit condition using a Solartron 1260 frequency response analyzer with a Solartron 1287 electrochemical interface. The frequency ranged from  $1 \times 10^6$  to 0.08 Hz with an amplitude of 10 mV.

Powder XRD patterns were collected in the  $2\theta$  range of 20–80 $^\circ$  on a Rigaku D/Max-2500/PC X-ray diffractometer operated at 40 kV and 200 mA using  $\text{Cu } K\alpha$  ( $\lambda = 0.15406 \text{ nm}$ ) radiation. The average crystallite size of the cubic phase was calculated from the Scherrer equation, where the Scherrer con-

stant (particle shape factor) was taken as 0.89. The SEM photographs of the  $\text{TiO}_2$ -modified LSCF cathode were taken with a JSM7800F microscope equipped with a field emission gun at 5 kV.

## 3. Results and discussion

### 3.1. XRD characterization

The interaction between LSCF and  $\text{TiO}_2$  was investigated by powder reaction. LSCF powder and  $\text{TiO}_2$  powder were mixed in a mass ratio of 4:1 and then calcined at various temperatures for 2 h. Figure 1 shows the XRD patterns of the LSCF- $\text{TiO}_2$  composite oxide calcined at 750–1050  $^\circ\text{C}$ . For the LSCF- $\text{TiO}_2$  composite oxide calcined at 750–800  $^\circ\text{C}$ , the characteristic peaks can be assigned to the perovskite LSCF phase and anatase phase of  $\text{TiO}_2$ . For the LSCF- $\text{TiO}_2$  composite oxide calcined at 850–1050  $^\circ\text{C}$ , the characteristic peaks of  $\text{SrTi}_{21}\text{O}_{38}$  and  $\text{CoFe}_2\text{O}_4$  started to appear in addition to the diffraction peaks of LSCF and  $\text{TiO}_2$ . These results suggested that the LSCF started to react with  $\text{TiO}_2$  at 850  $^\circ\text{C}$ . The average size of nano-crystallite  $\text{TiO}_2$ ,  $\text{SrTi}_{21}\text{O}_{38}$ , and  $\text{CoFe}_2\text{O}_4$  from the LSCF- $\text{TiO}_2$  mixture that was sintered at 850  $^\circ\text{C}$  was calculated by the Scherrer equation to be 35, 28, and 33 nm, respectively. In addition,  $\text{SrTiO}_3$  can be formed from the reaction between LSCF and  $\text{TiO}_2$ . Surface strontium enrichment on the LSCF, in the form of  $\text{SrO}$  or  $\text{Sr}(\text{OH})_2$ , is well known [16–20]. Sr-enriched LSCF can react with  $\text{TiO}_2$  to  $\text{SrTiO}_3$ . However, the  $\text{SrTiO}_3$  phase cannot be detected by XRD in the presence of the LSCF phase because of the same peak position of the perovskite LSCF phase and  $\text{SrTiO}_3$  phase. In order to show  $\text{SrTiO}_3$  formation,  $\text{TiO}_2$  was blended with  $\text{Sr}(\text{NO}_3)_2$  and calcined at 850  $^\circ\text{C}$  for 2 h. Figure 2 shows the XRD patterns of the  $\text{TiO}_2$ - $\text{Sr}(\text{NO}_3)_2$  composite with different molar ratio of Ti:Sr after calcination. For the molar ratios of Ti:Sr = 1:1, the diffraction peaks of the  $\text{SrTiO}_3$  and  $\text{Sr}_2\text{TiO}_4$  phases can be identified, indicating that  $\text{SrTiO}_3$  can be easily formed by the reaction of  $\text{TiO}_2$  with  $\text{SrO}$ . A similar conclusion was given for the reaction of Sr oxalate with  $\text{TiO}_2$  at 800  $^\circ\text{C}$  [21]. When the molar ratio of Ti:Sr was increased to 4:1,  $\text{Sr}_2\text{Ti}_6\text{O}_{13}$  phases were also identified besides the  $\text{SrTiO}_3$  and  $\text{Sr}_2\text{TiO}_4$  phases. These observations indicated that  $\text{SrTiO}_3$  could be

**Fig. 1.** XRD patterns of the LSCF- $\text{TiO}_2$  composite oxide calcined at 750 (1), 800 (2), 850 (3), 950 (4), and 1050  $^\circ\text{C}$  (5) for 2 h.
