Nickel oxide

ABSTRACT

A series of Co_xBa_{1.5}Ni₉ catalysts prepared by a co-precipitation method were investigated for N₂O decomposition. Co improved the activity of NiO when BaCO₃ was present but had the opposite role when it was absent. This was because Co strengthened the Ni–O bond and decreased the surface area when added into pure NiO without BaCO₃, while in the presence of BaCO₃, it dramatically increased the surface area and amount of active sites of NiO.

1. Introduction

Nitrous oxide (N₂O) destroys the ozone in the stratosphere and it is a strong greenhouse gas [1,2]. The continuous increase of its concentration in the atmosphere is mainly from the tail gas of adipic acid and nitric acid plants [3]. This calls for the developing of efficient catalysts for its decomposition into N₂ and O₂.

In recent years, 3d transition metal oxides such as Co₃O₄ [4–12], NiO [13,14], Fe₃O₄ [15], and CuO [16] have been shown to exhibit high activity for N₂O decomposition. Fundamental and applied research has focused on these materials, in particular on Co₃O₄ based materials. Many additives have been studied to improve the catalytic activity of Co₃O₄. The alkali metals Na⁺, K⁺, Cs⁺ [4,5,9–11] and alkaline earth metals Mg²⁺ [8], Ca²⁺, Ba²⁺ [12] and some other transition metals like Ce [6], Ni, Zn [7,8] have been reported to be effective. On the other hand, although NiO has a comparable catalytic activity to Co₃O₄ [11], fewer additives for it have been investigated, apart from Cs [13] and Ce [14]. Concerning the mechanism of the additive promo-

tion of the NiO catalyst, it was reported that Cs [13] significantly facilitated the desorption of the oxygen produced from N₂O decomposition by weakening the Ni–O bond. In the case of Ce as additive, the promotional effect was attributed to a significant increase of the catalyst surface area since it did not much strengthen the Ni–O bond [14]. This influence of Ce on NiO was confirmed in our previous work [17], and on this basis, we suggested that BaCO₃ not only played the same role as Cs, but also increased the surface area of the catalyst.

In the present work, a Co-modified NiO-BaCO₃ catalyst was studied, and a significant promotional effect by Co on the activity of NiO in the presence of BaCO₃ was found.

2. Experimental

All catalysts were prepared by the co-precipitation method with the following procedure. A Na₂CO₃ aqueous solution (0.2 mol/L) was added dropwise to a mixed solution containing known amounts of Ni(NO₃)₂·6H₂O and Ba(NO₃)₂ at 40 °C with strong stirring until the pH of the solution was 9.3. The slurry

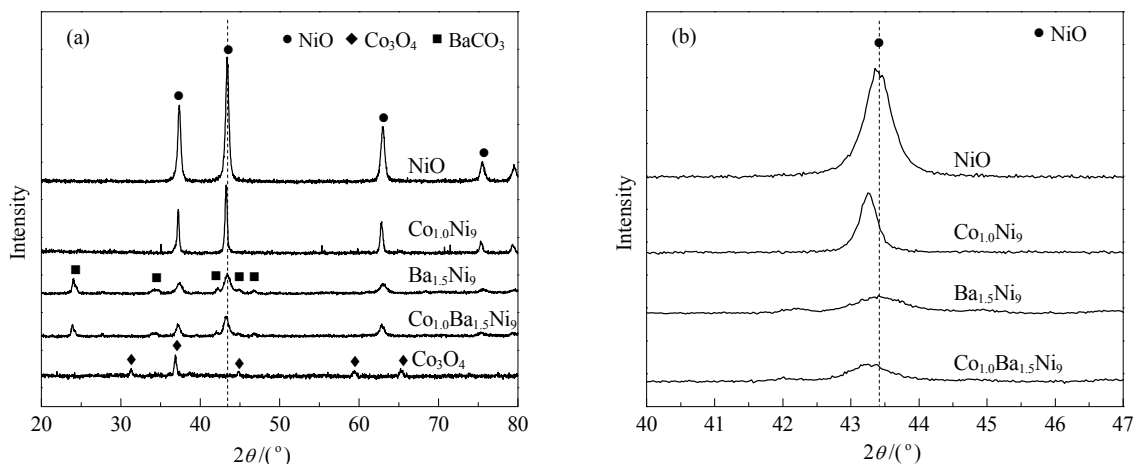

Fig. 1. (a) XRD patterns of the catalysts; (b) Amplification of the (200) (according to JCPDS 78-0643) reflection of NiO.

was stirred for an additional 2 h before it was filtered. Then the resultant precipitate was washed with distilled water until the pH of the filtrate reached 7. This sample was dried at 100 °C overnight, followed by calcination at 500 °C in air for 3 h. The catalysts were labeled as Co_xNi_9 or $\text{Co}_x\text{Ba}_{1.5}\text{Ni}_9$ according to the mole ratios of $\text{Co}(\text{NO}_3)_2 \cdot 6\text{H}_2\text{O}$ and $\text{Ba}(\text{NO}_3)_2$ to $\text{Ni}(\text{NO}_3)_2 \cdot 6\text{H}_2\text{O}$ in the mixed solution used for the catalyst preparation.

The characterization of the catalysts with X-ray diffraction, H_2 temperature-programmed reduction, O_2 temperature-programmed desorption, N_2 adsorption-desorption for measuring the BET surface area, and the activity tests were the same as our previous work [17].

3. Results and discussion

3.1. Structural properties

Figure 1 presents the XRD patterns of the catalysts. No diffraction peak belonging to Co_3O_4 or other cobalt oxide was observed on the $\text{Co}_{1.0}\text{Ni}_9$ and $\text{Co}_{1.0}\text{Ba}_{1.5}\text{Ni}_9$ catalysts, indicating that the cobalt was well dispersed on them. Moreover, the diffraction peaks of NiO for the $\text{Co}_{1.0}\text{Ni}_9$ and $\text{Co}_x\text{Ba}_{1.5}\text{Ni}_9$ catalysts were obviously shifted to lower angles as compared to pure NiO and $\text{Ba}_{1.5}\text{Ni}_9$, respectively. This resulted from the larger crystalline interplanar spacing of the (111), (200), (220), and (311) planes for $\text{Co}_{1.0}\text{Ni}_9$ and $\text{Co}_x\text{Ba}_{1.5}\text{Ni}_9$ with respect to their counterparts (Table 1). This is consistent with the radius of Co^{2+} (72 pm) > Ni^{2+} (69 pm). The result indicated that Co^{2+} was incorporated into the NiO phase and partially replaced Ni^{2+} in the $\text{Co}_{1.0}\text{Ni}_9$ and $\text{Co}_{1.0}\text{Ba}_{1.5}\text{Ni}_9$ catalysts. Table 1 shows the BET surface areas

of the catalyst samples. The surface area drastically decreased due to the formation of a solid solution (Co dissolved into NiO) in $\text{Co}_{1.0}\text{Ni}_9$. Interestingly, when BaCO_3 was in the catalyst, the opposite occurred. For $\text{Ba}_{1.5}\text{Ni}_9$ and $\text{Co}_{1.0}\text{Ba}_{1.5}\text{Ni}_9$, the specific surface areas were 32 and 41 m^2/g , respectively, indicating that Co was effective for increasing the surface area of the NiO- BaCO_3 catalyst.

3.2. Chemical properties

Figure 2 exhibits the H_2 -TPR profiles of the NiO, $\text{Co}_{1.0}\text{Ni}_9$, $\text{Ba}_{1.5}\text{Ni}_9$, and $\text{Co}_{1.0}\text{Ba}_{1.5}\text{Ni}_9$ catalysts. Three H_2 consumption peaks at 360, 408, and 435 °C appeared for pure NiO. The two peaks at the lower temperature were associated with the NiO reduction steps of $\text{NiO} \rightarrow \text{Ni}^{\delta+} \rightarrow \text{Ni}^{0.33}$ [14], while that at the higher temperature was due to the reduction of NiO and $\text{Ni}^{\delta+}$ inside larger NiO crystallites. Over $\text{Ba}_{1.5}\text{Ni}_9$, the last peak nearly did not appear, which was associated with the small crystallite size of NiO in the sample (Table 1). Compared to the pure NiO, all of the H_2 consumption peaks of $\text{Co}_{1.0}\text{Ni}_9$ were shifted to higher temperature, which reflects that Co in the solid solution suppressed the reduction of NiO. Nevertheless, the shift of the reduction peaks on $\text{Co}_{1.0}\text{Ba}_{1.5}\text{Ni}_9$ with respect to $\text{Ba}_{1.5}\text{Ni}_9$ was less than that due to the presence of BaCO_3 . This means that the
