### ABSTRACT

We describe the Neuroinformatics Database (NiDB), an open-source database platform for archiving, analysis, and sharing of neuroimaging data. Data from the multi-site projects Autism Brain Imaging Data Exchange (ABIDE), Bipolar–Schizophrenia Network on Intermediate Phenotypes parts one and two (B–SNIP1, B–SNIP2), and Monetary Incentive Delay task (MID) are available for download from the public instance of NiDB, with more projects sharing data as it becomes available. As demonstrated by making several large datasets available, NiDB is an extensible platform appropriately suited to archive and distributes shared neuroimaging data.

### Background

Neuroinformatics Database (NiDB) was created to solve the problem of organizing and analyzing very large neuroimaging datasets and has since grown into a neuroimaging database platform (Book et al., 2013). When development of the platform began in 2005, a publication with a sample size of one hundred subjects was considered very large, while now sample sizes in the thousands are common (Kiehl et al., 2005; Meda et al., 2014). There are diminishing returns when using sample sizes larger than 1000 subjects; however, the ability to store and analyze data from multiple patient cohorts and longitudinal datasets is extremely valuable, especially when testing reproducibility (Kennedy, 2014).

Development of NiDB began as a system for searching and downloading of MRI scans collected in the previous 30 days, using flat file storage of meta-data. The system could only search by subject ID, protocol name, and scan date. However, as the amount of stored data grew, the system was re-written to use a SQL database and catalog more meta-data. As data sizes grew further, the system architecture was redesigned to be subject-centric, following a Subject → Enrollment → Imaging Study → Series hierarchy (Fig. 1). A subject-centric design allows association of multiple modalities of data with an imaging session, multiple imaging sessions with a subject's enrollment in a project, and enrollment of subjects in multiple projects. This architecture provides a standardized hierarchy into which new imaging modalities are stored in the database and makes the addition of project permissions and security straightforward. NiDB currently stores magnetic resonance (MR), computed tomography (CT), ultrasound (US), positron-emission tomography (PET), electroencephalography

(EEG), pre-pulse inhibition (PPI), eye-tracking (ET), and genome data, but can expand with minimal effort to include any modality. NiDB is web-based, using PHP and JavaScript as the front-end, MySQL as the middle layer, and Perl as the backend. A separate uploader for large datasets is written in C++ and QT. Regular users access the system through the web-based GUI or QT based uploader, and administrators perform many maintenance operations through the web-based GUI. A small amount of maintenance is required in the back-end by a developer to backup data, add new modalities, fix bugs, or add enhancements. (See Fig. 2.)

Data importing, searching, and exporting features are available, as well as storage of subject demographics, system statistics, and project permissions. NiDB contains several features beyond data storage and searching, including: pipeline analysis, inter-instance sharing, and modular automated quality control (QC). Automated QC is 'modular', meaning a user can create a QC module/script which takes a data path as input, performs specified QC analysis, and inserts the results into the database. NiDB's pipeline system is connected to a compute cluster where analyses are automatically performed and results are imported back into the database to be associated with the original data. Data are analyzed using a normal bash script, with special NiDB variables that are replaced with full paths when the pipeline is run. Each pipeline has a set of data criteria, and all imaging studies that match the criteria are sent through the pipeline, which creates a custom cluster job with the correct paths and IDs for each imaging study. During the cluster job processing, output from the original bash script is logged and the status of an analysis can be viewed, along with summary statistics such as number completed, running, or in error state. Upon completion of each analysis, important results and figures (defined by the user) are automatically imported back into NiDB and are available for searching alongside the raw data. Data processed through a NiDB freesurfer pipeline was included in very large scale study of genetic association with subcortical brain structures (Hibar et al., 2015). The NiDB pipeline

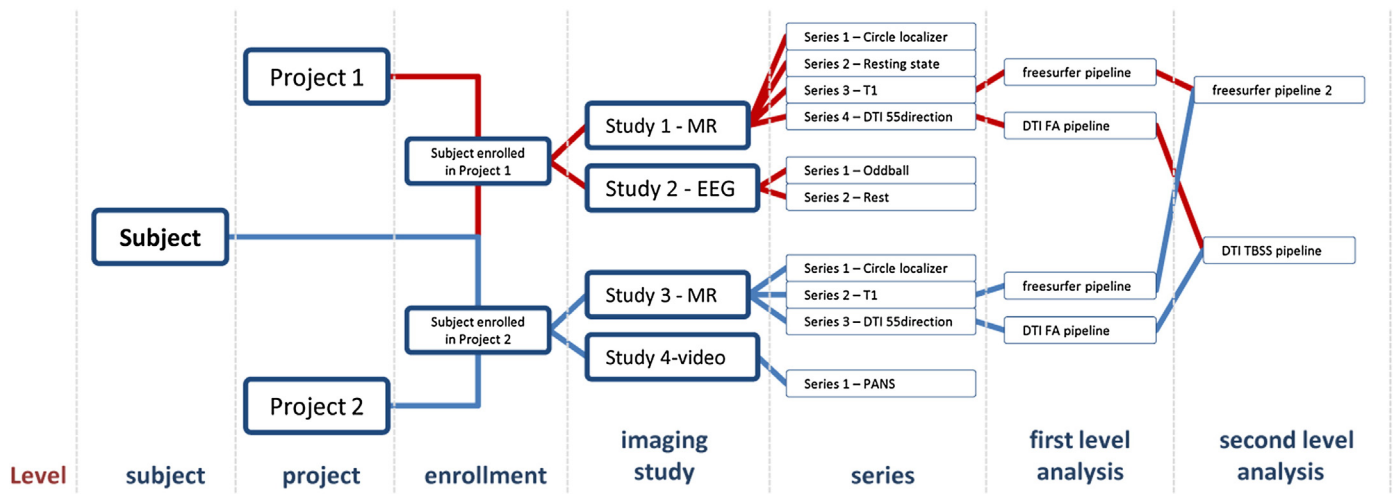

Fig. 1. Neuroinformatics database hierarchy. This is a near universal format into which any modality of imaging can be stored.

81 system includes inter-pipeline dependencies to allow efficient process-  
 82 ing of data. Examples of tested NiDB pipelines include freesurfer, SPM  
 83 fMRI processing, FSL DTI, FSL fMRI, and Human Connectome Pipeline  
 84 (HCP) analyses (Fig. 1).

85 A feature important to future data sharing is NiDB's export to  
 86 National Database on Autism Research (NDAR) format. NDAR is a  
 87 large scale data repository hosted by the NIMH, and the underlying  
 88 database system is now used for the Research Domain Criteria (RDoC)  
 89 project which seeks to archive data collected under NIMH sponsored  
 90 projects. NiDB compatibility with NDAR allows for direct, seamless  
 91 data export.

92 **Design**

93 The current iteration of NiDB was designed as an active study  
 94 management system for neuroimaging and clinical research data. Data  
 95 is imported from one of several sources (DICOM receiver, web-based  
 96 importer, GUI based importer, or inter-instance sharing), archived and  
 97 QC'd. The data is then searchable to users. Archived data is associated  
 98 with existing or new subjects, at which time demographic data may  
 99 be imported from meta-data (eg DICOM header) or manually entered.  
 100 Data stored on the public server is static for the main projects listed in  
 101 the available data section, but may be dynamic for other projects.

**Available data**

120

121 NiDB is currently hosted in two different instances, each with differ-  
 122 ent data and accessibility. The internal instance of NiDB, only accessible  
 123 within the Olin Neuropsychiatry Research Center network, contains  
 124 12.9 TB of raw data from 199,951 imaging series from 22,464 imaging  
 125 sessions from 11,147 subjects in 158 projects. In total, 366 days of CPU  
 126 time have been used to compute QC metrics and 16.6 TB of data have  
 127 been requested. While these data are not all available publicly, it attests  
 128 to the scalability of NiDB. The external (public) instance of NiDB con-  
 129 tains the data described in this paper, available at <http://olinnidb.org>  
 130 (Table 1). Five major projects comprise the data currently shared on  
 131 the public server: ABIDE, B-SNIP1, PARDIP, B-SNIP2, MID.

132 Autism Brain Imaging Data Exchange (ABIDE) data was aggregated  
 133 by the International Data-sharing Initiative (INDI) and imported into  
 134 NiDB (Di Martino et al., 2014; Mennes et al., 2013). The ABIDE dataset  
 135 contains resting fMRI, structural MR, and phenotypic data from 16  
 136 projects (sites) examining autism spectrum disorder. The original  
 137 downloads from ABIDE were single blocks of data from each site, but  
 138 after importing into NiDB, subsets of the data can be searched for and  
 139 downloaded. Part one of the Bipolar-Schizophrenia Network on Inter-  
 140 mediate Phenotypes (B-SNIP1) study, examines multiple phenotypes  
 141 in individuals with schizophrenia, psychotic bipolar disorder, and  
 142 schizoaffective disorder, and their first-degree relatives. Data were col-
