Opioid peptides

Gonadotropin-releasing hormone

Galanin

Vasoactive intestinal peptide

Cholecystokinin

Angiotensin II

Hypocretins/orexins

VGF-derived peptides

ABSTRACT

Of the numerous neuropeptides identified in the central nervous system, only a few are involved in the control of sexual behaviour. Among these, the most studied are oxytocin, adrenocorticotropin, α -melanocyte stimulating hormone and opioid peptides. While opioid peptides inhibit sexual performance, the others facilitate sexual behaviour in most of the species studied so far (rats, mice, monkeys and humans). However, evidence for a sexual role of gonadotropin-releasing hormone, corticotropin releasing factor, neuropeptide Y, galanin and galanin-like peptide, cholecystokinin, substance P, vasoactive intestinal peptide, vasopressin, angiotensin II, hypocretins/orexins and VGF-derived peptides are also available. Corticotropin releasing factor, neuropeptide Y, cholecystokinin, vasopressin and angiotensin II inhibit, while substance P, vasoactive intestinal peptide, hypocretins/orexins and some VGF-derived peptide facilitate sexual behaviour. Neuropeptides influence sexual behaviour by acting mainly in the hypothalamic nuclei (i.e., lateral hypothalamus, paraventricular nucleus, ventromedial nucleus, arcuate nucleus), in the medial preoptic area and in the spinal cord. However, it is often unclear whether neuropeptides influence the anticipatory phase (sexual arousal and/or motivation) or the consummatory phase (performance) of sexual behaviour, except in a few cases (e.g., opioid peptides and oxytocin). Unfortunately, scarce information has been added in the last 15 years on the neural mechanisms by which neuropeptides influence sexual behaviour, most studied neuropeptides apart. This may be due to a decreased interest of researchers on neuropeptides and sexual behaviour or on sexual behaviour in general. Such a decrease may be related to the discovery of orally effective, locally acting type V phosphodiesterase inhibitors for the therapy of erectile dysfunction.

13 **1. Introduction**

14 Sexual behaviour plays a main role in reproduction of all living
15 animals, from insects to mammals, including humans. In
16 mammals, it is commonly accepted that it is organized in two
17 main phases, anticipatory and consummatory, and several
18 quantifiable parameters have been identified in each phase and
19 in both males and females. These studies were conducted mainly in
20 rats because of their availability, the well characterized sequence
21 of copulatory behaviour and its parameters in the male (for a
22 detailed description of the male rat copulatory behaviour see
23 Bitran and Hull, 1987; Sachs, 1978; Sachs and Meisel, 1988, 1994;
24 Q4 Hull et al., 2002), and of proceptive and receptive (lordotic)
25 Q5 behaviour in the female (see Caggiola et al., 1976, 1979), although
26 data on some other animal species are also available (Absil et al.,
27 1994). Penile erection, seminal emission and ejaculation charac-
28 terize the consummatory phase of the male sexual response, while
29 vaginal lubrication, clitoris erection and orgasm are typical of the
30 female sexual response. These consummatory responses are
31 preceded by an anticipatory, mainly appetitive phase, which
32 includes motivation towards and searching of an adequate partner
33 for copulation (see Sachs and Meisel, 1988; Meisel and Sachs,
34 1994). Also in humans the sexual response is organized in distinct
35 and sequential phases, which include usually (but not always)
36 sexual desire followed by sexual arousal and orgasm, including
37 ejaculation in males, when a partner is available for sexual
38 intercourse, although an integration of these phases is likely to
39 exist (see Masters and Johnson, 1966; Kaplan, 1979; Leiblum,
40 Q6 1998). Briefly, when sexual (visual, auditory, olfactory, tactile and
41 in humans even imaginative) stimuli reach the central nervous
42 system, neural pathways are activated which convey sexual
43 information from the higher brain centres through the spinal cord
44 and the autonomous nervous system to the genital apparatus to
45 induce penile erection in males and vaginal lubrication/clitoris
46 erection in female in order to make sexual intercourse, which will
47 Q7 culminate with orgasm, feasible (see Meisel and Sachs, 1994; Lue
48 and Tanagho, 1987; Burnett et al., 1992; Raifer et al., 1992;
49 Andersson and Wagner, 1995; Argiolas and Melis, 1995; Argiolas,
50 2005 and references therein) (Fig. 1). It is well known that
51 numerous neurotransmitters and neuropeptides are involved at
52 central and peripheral level in the control of the above phases of

sexual behaviour. Among neuropeptides, oxytocin, adrenocortico-
53 tropin (ACTH), α -melanocyte stimulating hormone (α -MSH) and
54 opioid peptides are the most studied (see Bertolini and Gessa,
55 1981; Pfau and Gorzalka, 1987; Dornan and Malsbury, 1989;
56 Argiolas, 1999). These neuropeptides exert their effect on sexual
57 behaviour by acting mainly in the hypothalamus and its nuclei
58 (e.g., lateral hypothalamus, paraventricular nucleus, ventromedial
59 nucleus, arcuate nucleus), the medial preoptic area and in other
60 brain areas as well (e.g., the ventral tegmental area, the
61 hippocampus, the amygdala, the medulla oblongata and the spinal
62 cord), where they often interact in a concerted manner with
63 classical neurotransmitters, such as dopamine, glutamic acid,
64 gamma-aminobutyric acid (GABA), nitric oxide and others to
65 influence either sexual performance or sexual motivation and
66 arousal or both (see Argiolas and Melis, 2004, 2005; Melis and
67 Argiolas, 2011; Andersson, 2011; Baskerville and Douglas, 2008;
68 Baskerville et al., 2009). However, evidence also exists for a role of
69 gonadotropin-releasing hormone (GnRH or LHRH), corticotropin
70 releasing factor (CRF), vasoactive intestinal peptide, neuropeptide
71 Y, galanin, galanin-related peptide, cholecystokinin, substance P
72 and neurokinins, vasopressin, angiotensins and hypocretins/
73 orexins (see Argiolas, 1999; Dornan and Malsbury, 1989). A
74 possible role for a few other peptides, such as VGF-derived
75 peptides and endogenous growth hormone (GH) peptide secreta-
76 gogues in the control of specific aspects of sexual behaviour,
77 mainly penile erection, also has been suggested (see Argiolas and
78 Melis, 2005) (Tables 1 and 2).
79
80 The aim of this work is to review the literature on the central role
81 of the above and newly discovered neuropeptides on sexual
82 behaviour analysed possibly in its main phases, anticipatory and
83 consummatory (see Bitran and Hull, 1987; Meisel and Sachs, 1994;
84 Melis and Argiolas, 1995a; Hull et al., 2002), in the male and female
85 animals of the species more studied so far (e.g. rats, mice, monkeys)
86 and when available, also in humans and in other mammals. Since the
87 literature on the sexual role of some of the above neuropeptides at
88 the central level has been extensively reviewed up to 1999 (Bertolini
89 and Gessa, 1981; Pfau and Gorzalka, 1987; Dornan and Malsbury,
90 1989; Richard et al., 1991; Argiolas and Gessa, 1992; Carter, 1992;
91 Meisel and Sachs, 1994; Argiolas, 1999), particular attention was Q8
92 given to the studies appeared since 2000 up to today on the role of
93 oxytocin, ACTH–MSH peptides, opioid peptides and GnRH, because
