HIGHLIGHTS

- Compound-specific stable isotopes (CSSIs) of carbon may be used as soil tracers.
- The variables affecting CSSI data are: biological, environmental and analytical.
- Understanding sources of variability will lead to more robust methods and data.
- Recommendations for applying CSSIs to soil and sediment tracing are provided.

ABSTRACT

Determining soil redistribution and sediment budgets in watersheds is often challenging. One of the methods for making such determinations employs soil and sediment fingerprinting techniques, using sediment properties such as geochemistry, fallout radionuclides, and mineral magnetism. These methods greatly improve the estimation of erosion and deposition within a watershed, but are limited when determining land use-based soil and sediment movement. Recently, compound-specific stable isotopes (CSSIs), which employ fatty acids naturally occurring in the vegetative cover of soils, offer the possibility of refining fingerprinting techniques based on land use, complementing other methods that are currently in use.

The CSSI method has been met with some success; however, challenges still remain with respect to scale and resolution due to a potentially large degree of biological, environmental and analytical uncertainty. By better

understanding the source of tracers used in CSSI work and the inherent biochemical variability in those tracers, improvement in sample design and tracer selection is possible. Furthermore, an understanding of environmental and analytical factors affecting the CSSI signal will lead to refinement of the approach and the ability to generate more robust data. This review focuses on sources of biological, environmental and analytical variability in applying CSSI to soil and sediment fingerprinting, and presents recommendations based on past work and current research in this area for improving the CSSI technique. A recommendation, based on current information available in the literature, is to use very-long chain saturated fatty acids and to avoid the use of the ubiquitous saturated fatty acids, C₁₆ and C₁₈.

1. Soil and sediment fingerprinting: an overview

1.1. Water security and ecosystem health

Rivers are the primary source of renewable fresh water supply (Vörösmarty et al., 2010), and thus are fundamental for ensuring water security. The activities of landholders have been identified as one of the water management factors that contribute to the degradation of water quality (Sarker et al., 2008). In the United States, agricultural fields have been determined to be the greatest contributor to diffuse source pollution (DSP) (Pimentel et al., 2004), resulting in water quality loss due to soil erosion and run-off of nutrients, sediments and pesticides (Pimentel et al., 2004; Sarker et al., 2008); indeed, agricultural land use has been found to be the predominant stressor on catchments globally (Vörösmarty et al., 2010). A need therefore exists to address and manage the DSPs that lead to water quality degradation and threaten water security.

Although some aquatic organisms may be tolerant and able to adapt to a range and highly variable amount of fine sediment (Henley et al., 2000), increased fine sediment¹ loads entering a body of water may have undesirable chemical and physical effects on the aquatic environment. Physical effects include a decrease in light penetration, accumulation of sediment leading to decreased accessibility of waterways, and increased purification costs if the water body is being used as a drinking source (Owens et al., 2005; Bilotta and Brazier, 2008; Horowitz, 2008). An increase in sediment deposition is also an indication of terrestrial erosion and soil loss (Horowitz, 2008). Human activities such as deforestation, agriculture, construction and mining have been shown to be major contributors to increased deposition and transport of fine

¹ Finer particle sizes are more apt for suspension and transport in aquatic systems; particle sizes of <63 µm are important for the transport and storage of contaminants and nutrients (Owens et al., 2005).
