This is a PDF file of an unedited manuscript that has been accepted for publication. As a service to our customers we are providing this early version of the manuscript. The manuscript will undergo copyediting, typesetting, and review of the resulting proof before it is published in its final form. Please note that during the production process errors may be discovered which could affect the content, and all legal disclaimers that apply to the journal pertain.

Highlights

- The paper develops a realistic model for the spatiotemporal evolution of atrachnose disease prevalence in a bounded two- or three-dimensional domain. The model includes the possibility of two types of control strategy: chemical (modeled using a continuous control function) and cultivational (modeled as discrete pulses).
- The paper establishes well-posedness of the model, as well as the existence of optimal impulsive and mixed strategies.
- The paper proves and simulates an explicit algorithm for obtaining an optimal impulsive strategy.
- The paper shows that in some cases a simplified averaged model can be used to characterize system behavior and to obtain an optimal impulsive strategy.
