### ABSTRACT

Growing concern about sulfur dioxide (SO<sub>2</sub>) poisoning NO<sub>x</sub> removal catalysts has resulted in the development of desulfurization materials for SO<sub>2</sub> trap. In this study, a series of high-specific-surface-area manganese oxide (HSSA MnO<sub>2</sub>) were selected as desulfurization materials and characterized by nitrogen adsorption and SEM. HSSA MnO<sub>2</sub> has good SO<sub>2</sub> capture performance over a wide temperature range. At low temperature, SO<sub>2</sub> capture capacity and adsorption rate increase with the specific surface area and HSSA MnO<sub>2</sub> showed high SO<sub>2</sub> capture performance. The effect of temperature on sulfate rate of HSSA MnO<sub>2</sub> can be explained by the grain model. The gradient of sulfate rate constant decreases with increasing the reaction temperature, and there is a sudden drop at 500 °C. The SO<sub>2</sub> capture performance of regenerated HSSA MnO<sub>2</sub> decreases sharply because of physical damage by calcination at high temperature.

### 1. Introduction

Sulfur dioxide (SO<sub>2</sub>) from diesel exhaust is one of the main air pollutants. Besides, SO<sub>2</sub> from exhaust gas always poisons the sulfur-sensitive NO<sub>x</sub> removal catalysts, especially the lean NO<sub>x</sub> trap (LNT) in the diesel exhaust system. It is reported that the capacity of LNT is strongly reduced by SO<sub>2</sub>, because sulfates are more stable than nitrates [1–4]. In tradition, the main way to remove SO<sub>2</sub> from diesel exhaust is fuel upgrades by hydrodesulfurization. However, it is still a challenge to find appropriate solutions to prevent NO<sub>x</sub> removal catalyst from being exposed to SO<sub>2</sub> for the sulfur content of diesel varying from tens of ppm to hundreds of ppm.

Currently, compact SO<sub>2</sub> trap upstream of NO<sub>x</sub> conversion device has been proposed to improve the longevity of NO<sub>x</sub> removal catalysts against SO<sub>2</sub> poisoning in the diesel exhaust system [5–9]. The SO<sub>2</sub> discharge is about 160 g (10 ppm sulfur in diesel) for about 30,000 km of one year for a diesel engine, and the levels of sulphation for SO<sub>2</sub> trap should be at least 20% of weight increase. However, the traditional materials, such as calcined limestone [10], MgO [11] and hydrotalcite-like compounds [12,13], don't have enough SO<sub>2</sub> trap capacity for their application in compact SO<sub>2</sub> trap.

Therefore, new materials with sufficient performances should be developed.

With the diesel engine technology developed, the maximum temperature of diesel exhaust is decreased and the temperature is limited from 200 °C to 500 °C. Unfortunately, limited studies have been reported in the literature on desulfurization materials with low temperature activation. Kasaoka et al. [14] focused on improving the reaction activity using complexes based on CuO at 350 °C. Tseng and Wey [15] investigated the SO<sub>2</sub> oxidation activity of copper oxide supported on activated carbon at the range of limited temperature between 200 °C and 450 °C. Rubio and Izquierdo [16] studied the SO<sub>2</sub> removal performance of coal fly ash based carbons at flue gas conditions and the amount of SO<sub>2</sub> removed is 13 mg/g by the Lada activated sample at 100 °C and the present of 1000 ppmv SO<sub>2</sub>, 5% O<sub>2</sub>, 6% H<sub>2</sub>O gas conditions after 24 h. Nishioka and Yoshida [17] investigated the reaction activity of SO<sub>2</sub> trap catalyst with a noble metal under low temperature conditions and the amount of trapped sulfur is about 18 g/2 l-catalyst at 250 °C. Kylhammar et al. [18] investigated the SO<sub>2</sub> trapping capacity of CeO<sub>2</sub>-based materials at 250 °C and the fresh sample can storage about 19 mg<sub>SO2</sub>/g<sub>CeO2</sub>. In these studies, the SO<sub>2</sub> trap capacities of materials are very small in low temperature range.

In the previous studies [19], it has been found that the CaCO<sub>3</sub> materials have good reactivity with SO<sub>2</sub> at 650 °C. However, the sulfation rate declines under low temperature conditions for the

## Nomenclature

$P$	$\text{SO}_2$ capture performance per unit mass, $\text{g}_{\text{SO}_2}/\text{g}_{\text{material}}$	$k$	reaction rate constant, $\text{cm}^4/(\text{mol s})$
$s$	weight, mg	$r$	radius at reaction surface, cm
$t$	time, s	$R$	radius of spherical grain, cm
$X$	reaction ratio, %	$\varepsilon$	void fraction, %
$M$	amount of material, g/mol		
$C$	molar concentration of $\text{SO}_2$ , $\text{mol}/\text{cm}^3$		

reason that the sulfate reaction activity may be limited by the decarbonation. The  $\text{SO}_2$  trapping performance of materials with different physical properties (for example particle diameter, pore diameter distribution and specific surface area) has been investigated [20–22]. From these studies, under low temperature conditions the materials with high specific surface area and simple reaction mechanism exhibit good  $\text{SO}_2$  trapping performance. Manganese oxide with high specific surface area (HSSA  $\text{MnO}_2$ ) and a simple sulfate reaction path ( $\text{MnO}_2 + \text{SO}_2 \rightarrow \text{MnSO}_4$ ) was focused on as a candidate for the materials of desulfurization filter in low temperature region [23,24].

Furthermore, in the present work, basic  $\text{SO}_2$  capture performance of was measured by a thermogravimetry (TG) device. Then, the influences of specific surface area on  $\text{SO}_2$  capture performance of HSSA  $\text{MnO}_2$  at low temperature were investigated under a wide temperature range of diesel exhaust. The sulfate rate constant was estimated at various reaction temperatures by using grain model. Finally,  $\text{SO}_2$  capture performance of fresh and regenerable HSSA  $\text{MnO}_2$  was investigated.

## 2. Experimental

### 2.1. Materials

The HSSA  $\text{MnO}_2$  used for experiments was supplied by Japan Material and Chemical Co., Ltd. These materials were obtained by the acid treatment of raw material. In the experiments, HSSA  $\text{MnO}_2$  materials with specific surface area  $155 \text{ m}^2/\text{g}$ ,  $200 \text{ m}^2/\text{g}$ ,  $257 \text{ m}^2/\text{g}$  and  $300 \text{ m}^2/\text{g}$  were selected. Commercial  $\text{MnO}_2$  from Kanto Chemical Co., Inc. (specific surface area of  $20 \text{ m}^2/\text{g}$ ) was used as a reference.

In this study, the specific surface area, pore volume distribution, and surface structure were analyzed to assess the physical characteristics of the target materials. The specific surface area of these samples was measured by the Brunauer–Emmett–Teller (BET) with the nitrogen adsorption uptake at the boiling point of nitrogen of 77 K using a capacitive measurement method. The pore-diameter was measured by nitrogen physisorption under normal relative pressure of 0.1–1.0 using the Barrett–Joyner–Halenda (BJH) method. Surface observation of the samples was conducted by scanning electron microscopy (SEM). The particle size distribution of the selected materials was determined by Malvern laser particle size analyzer.

Fig. 1 shows the distribution of pore diameter of HSSA  $\text{MnO}_2$  with different specific surface area. The specific surface area of selected samples is  $155 \text{ m}^2/\text{g}$ ,  $200 \text{ m}^2/\text{g}$  and  $257 \text{ m}^2/\text{g}$ , respectively. From the results of Fig. 1, the relatively large pore-diameter of all samples ranges from 40 Å to 100 Å. The micrograph of HSSA  $\text{MnO}_2$  is displayed in Fig. 2. The formed-grain HSSA  $\text{MnO}_2$  is seen to be made up of non-uniformly smooth spherical particles with a small size of 1  $\mu\text{m}$  and the particle size of the materials ranges from 0.76  $\mu\text{m}$  to 2.51  $\mu\text{m}$ , as seen in Table 1.

Fig. 1. Distribution of pore diameter of HSSA  $\text{MnO}_2$  with different specific surface area:  $155 \text{ m}^2/\text{g}$ ,  $200 \text{ m}^2/\text{g}$  and  $257 \text{ m}^2/\text{g}$ .

### 2.2. Thermogravimetric measurements

Thermogravimetry (TG) was used in this study to measure the effectiveness of the sulfate reaction of HSSA  $\text{MnO}_2$ . Fig. 3 shows a schematic drawing of the TG analysis experiment. The amount 50 mg of a sample on a quartz crucible was slowly (10 K/min) heated to the target temperature in the atmosphere of nitrogen, and maintained this condition for about 2 h. Reactant gas flow (500 ppm  $\text{SO}_2$  in base  $\text{N}_2$ ) was controlled by mass flow controller. The total flow gas rate was 2 l/min. During  $\text{SO}_2$  adsorption, the gas stream was passed over the sample at target temperature for 2 h. The reaction temperature of the TG experiment ranged from 100 °C to 600 °C.

The  $\text{SO}_2$  capture performance of samples was measured. The  $\text{SO}_2$  capture performance per unit mass  $P$  and the conversion of samples  $X(t)$  are expressed by the following equations:

$$P = \frac{s_t - s_0}{s_0} [\text{g}_{\text{SO}_2}/\text{g}_{\text{MnO}_2}] \quad (1)$$

$$X(t) = \frac{M_{\text{MnO}_2}}{M_{\text{SO}_2}} \cdot \frac{s_t - s_0}{s_0} [\text{g}_{\text{SO}_2}/\text{g}_{\text{MnO}_2}] \quad (2)$$

$P$  is the  $\text{SO}_2$  capture performance per unit mass [ $\text{g}_{\text{SO}_2}/\text{g}_{\text{MnO}_2}$ ],  $s_0$  is the initial weight [mg], and  $s_t$  is the weight after  $t$  seconds [mg],  $M_{\text{MnO}_2}$  is the molar mass of  $\text{MnO}_2$  [g/mol],  $M_{\text{SO}_2}$  is the molar mass of  $\text{SO}_2$  [g/mol].

## 3. Results and discussion

### 3.1. Basic sulfate performance of HSSA $\text{MnO}_2$ particle

Fig. 4 shows the influence of sulfate reaction temperature on  $\text{SO}_2$  capture performance of HSSA  $\text{MnO}_2$ . The  $\text{SO}_2$  capture
