## ABSTRACT

The Euclidean minimum  $M(K)$  of a number field  $K$  is an important numerical invariant that indicates whether  $K$  is norm-Euclidean. When  $K$  is a non-CM field of unit rank 2 or higher, Cerri showed  $M(K)$ , as the supremum in the Euclidean spectrum  $\text{Spec}(K)$ , is isolated and attained and can be computed in finite time. We extend Cerri's works by applying recent dynamical results of Lindenstrauss and Wang. In particular, the following facts are proved:

- (1) For any number field  $K$  of unit rank 3 or higher,  $M(K)$  is isolated and attained and Cerri's algorithm computes  $M(K)$  in finite time.
- (2) If  $K$  is a non-CM field of unit rank 2 or higher, then the computational complexity of  $M(K)$  is bounded in terms of the degree, discriminant and regulator of  $K$ .

## 1. Introduction

### 1.1. Background

A number field  $K$  is said to be norm-Euclidean if its ring of integers  $\mathcal{O}_K$  is a Euclidean domain with respect to the algebraic norm  $|N_K(\cdot)|$ , that is, for all  $x, y \in \mathcal{O}_K$ , there exists  $a \in \mathcal{O}_K$  such that  $|N_K(x - ay)| < |N_K(y)|$ . The Euclidean minimum of  $K$  is a numerical indicator of whether  $K$  is norm-Euclidean or not.

**Definition 1.1.** The *Euclidean minimum* of an element  $x \in K$  is  $m_K(x) = \inf_{y \in x + \mathcal{O}_K} |N_K(y)|$ .

The *Euclidean spectrum* of the number field  $K$  is the image  $\{m_K(x) : x \in K\}$  and the *Euclidean minimum* of  $K$  is  $M(K) = \sup_{x \in K} m_K(x)$ .

It is known that  $K$  is norm-Euclidean if  $M(K) > 1$  and is not norm-Euclidean if  $M(K) < 1$ . When  $M(K) = 1$ , it was proved by Cerri [Cer06] that if the unit rank of  $K$  is at least 2 then it is not norm-Euclidean.

One can easily check that  $m_K(x) \geq 0$  and  $M(K) > 0$ . When  $K$  is totally real it is part of a conjecture of Minkowski that  $M(K) \leq 2^{-d} \sqrt{D_K}$  where  $d$  and  $D_K$  denote respectively the degree and discriminant of  $K$ . The conjecture has been proved only for number fields of low degrees. However, weaker general upper bounds are available: for totally real fields Chebotarev proved  $M(K) \leq 2^{-\frac{d}{2}} \sqrt{D_K}$  (see for example [HW79, §24.9]). For general number fields (not necessarily totally real), Bayer Fluckiger showed in [BF06] that

$$M(K) \leq 2^{-d} D_K. \tag{1.1}$$

In the rest of this paper, we will always write

$$\overline{K} = K \otimes_{\mathbb{Q}} \mathbb{R}. \tag{1.2}$$
