Attenuation characteristics in eastern Himalaya and southern Tibetan Plateau:
an understanding of the physical state of the medium

14 **Abstract**

15 Attenuation characteristics of the crust in the eastern Himalaya and the south-
 16 ern Tibetan Plateau are investigated using high quality data recorded by Hi-
 17 malayan Nepal Tibet Seismic Experiment (HIMNT) during 2001-2003. The
 18 present study aims to provide an attenuation model that can address the physi-
 19 cal mechanism governing the attenuation characteristics in the underlying medium.
 20 We have studied the *Coda* wave attenuation (Q_c) in the *single isotropic scatter-*
 21 *ing model* hypothesis, *S* wave attenuation (Q_s) by using the *coda normalization*
 22 *method* and intrinsic (Q_i^{-1}) and scattering (Q_{sc}^{-1}) quality factors by the *multi-*
 23 *ple Lapse Time Window Analysis (MLTWA)* method under the assumption of
 24 multiple isotropic scattering in a 3-D half space within the frequency range 2-12
 25 Hz. All the values of Q exhibit frequency dependent nature for a seismically
 26 active area. At all the frequencies intrinsic absorption is predominant compared
 27 to scattering attenuation and seismic albedo (B_0) are found to be lower than
