22 **Abstract**

23 Hydrostatic pressure effects on magnetic parameters for crustal rock have been
24 poorly investigated yet, while it is important for an understanding of source of long-
25 wavelength magnetic anomaly, which is considered to reside in deep crust. In this study
26 we have conducted the *in-situ* magnetic hysteresis measurements on multidomain (MD)
27 magnetite under high pressure up to 1 GPa. With special attention to hydrostatic
28 condition and sample preparation, pressure dependences of its magnetic hysteresis
29 parameters (saturation magnetization, M_s ; saturation remanence, M_{rs} ; coercivity, B_c ;
30 coercivity of remanence, B_{cr}) are revealed as follows: (1) B_c monotonically increases
31 with pressure at a rate of +91 %/GPa; (2) M_s is constant under high pressure up to 1
32 GPa; and (3) M_{rs} increases with pressure up to 0.5 GPa by ~30 % and reaches to
33 saturation above the pressure; (4) B_{cr} is nearly constant at low pressure, and it increases
34 above ~0.6 GPa; and (5) the changes in ratios M_{rs}/M_s and B_{cr}/B_c correlate with each
35 other, resulting in systematic movement on the Day plot. These findings allow us to
36 estimate change in a relaxation time of magnetic remanence carried by MD magnetite as
