## ABSTRACT

Electrochemical sensors and supercapacitors are two noteworthy applications of electrochemistry. Herein, we report the synthesis of  $\text{SnFe}_2\text{O}_4$  microcubes and  $\text{Fe}_2\text{O}_3$  nanorods through a facile microwave assisted technique which are employed in fabricating the electrodes for nonenzymatic hydrogen peroxide ( $\text{H}_2\text{O}_2$ ) sensor and supercapacitor applications.  $\text{SnFe}_2\text{O}_4$  microcubes exhibited an enhanced specific capacitance of  $172 \text{ Fg}^{-1}$  at a scan rate of  $5 \text{ mVs}^{-1}$  in comparison to  $\text{Fe}_2\text{O}_3$  nanorods ( $70 \text{ Fg}^{-1}$ ). Furthermore, the  $\text{H}_2\text{O}_2$  sensing performance of the fabricated  $\text{SnFe}_2\text{O}_4$  electrodes through chronopotentiometry studies in 0.1 M PBS solution (at pH 7) with a wide linear range revealed a good sensitivity of  $2.7 \text{ mV } \mu\text{M}^{-1} \text{ } \mu\text{g}^{-1}$  with a lowest detection limit of 41 nM at a signal-to-noise ratio of 3. These results indicate that  $\text{SnFe}_2\text{O}_4$  microcubes are excellent materials for the cost effective design and development of efficient supercapacitors as well as nonenzymatic sensors.

## 1. Introduction

Transition metal oxides are one of the most fascinating class of materials among inorganic solids owing to the multitude of properties they exhibit and their cost effective scalable synthesis [1]. Spinel ferrites of the form  $\text{MFe}_2\text{O}_4$  ( $\text{M} = \text{Co}^{2+}$ ,  $\text{Ni}^{2+}$ ,  $\text{Mn}^{2+}$ ,  $\text{Sn}^{2+}$ , etc.) are a small group of transition metal oxide compounds that are primarily derived from magnetite ( $\text{Fe}_3\text{O}_4$ ). The unique electrical and magnetic properties of spinel ferrites have attracted a wide range of applications such as high-density data storage, heterogeneous catalysis, optical limiting, sensors, spintronics, magnetocaloric refrigeration, magnetic labeling in immunoassays, guided drug delivery, magnetic resonance imaging and hyperthermia of cancer cells [2–10].

Spinel ferrites have also been utilized for applications in electrochemistry such as lithium ion batteries, supercapacitors, electrochemical sensors, etc. [11–14]. Supercapacitors are electrochemical capacitors with high power density and fast charge-discharge performances that are essentially important for reducing the global reliance on exhaustible natural resources and curbing

their environmentally hazardous pollutants. Pseudo-capacitors (redox capacitors) are the subcategories of supercapacitors, in which the active material undergoes redox reactions and enhances the specific capacitance of the supercapacitor [15]. On the other hand, electrochemical sensors are significantly important for biomedical applications such as the detection of various analyte molecules such as hydrogen peroxide, glucose, dopamine etc. [13,16]. Among electrochemical techniques, chronopotentiometry is one of the promising techniques in which the change in concentration of the additive results in potential drifts that can be calibrated and used for the sensing applications. Potentiometric sensors usually have the wide linear range and lower limit of detection [17–19].

Amidst many different analytes, detection of hydrogen peroxide ( $\text{H}_2\text{O}_2$ ) is significantly important owing to its usage in various fields such as environmental, food, pharmaceutical, clinical analysis and biological processes. Among various techniques of  $\text{H}_2\text{O}_2$  detection such as spectrometry, titrimetry, chemiluminescence and electrochemical, the electrochemical approach is the most accurate, fast and cost effective [20–22]. Electrochemical detection approach can be subdivided into two categories viz., enzymatic and nonenzymatic. Though enzymatic approach is capable of detecting relatively low concentrations of  $\text{H}_2\text{O}_2$  with good sensitivity, they are a failure due to the expensive cost of enzymes, their instability and challenging immobilization process. The failures of enzymatic

sensors have been successfully addressed through nonenzymatic sensors fabricated using various materials on modified electrodes. However, obtaining very high sensitivity together with lowest detection limit on modified electrodes is a challenging task.

Spinel ferrites and their composites can potentially electrocatalyze the reduction of  $\text{H}_2\text{O}_2$ . The stable spinel structure of ferrites contributes the solid state redox couples like  $\text{M}^{3+}/\text{M}^{2+}$  and  $\text{Fe}^{3+}/\text{Fe}^{2+}$  enables their active participation in the electrochemical reaction for increasing the rate of electron transfer [23–25]. The lower redox potential of Sn in stannous ferrite ( $\text{SnFe}_2\text{O}_4$ ) is expected to provide  $\text{Sn}^{4+}/\text{Sn}^{2+}$  along with  $\text{Fe}^{3+}/\text{Fe}^{2+}$  as redox couples for effectively catalyzing the reduction of  $\text{H}_2\text{O}_2$ , which suggests that  $\text{SnFe}_2\text{O}_4$  is a promising material for electrochemical applications. In this context, the main aim of the present work is to synthesize  $\text{SnFe}_2\text{O}_4$  through a simple approach and explore its application as electrodes for supercapacitors and nonenzymatic sensors. Also, to the best of our knowledge there are no reports available in the literature on the synthesis of  $\text{SnFe}_2\text{O}_4$  through microwave assisted approach and its applications in supercapacitors or sensors. In this regard, herein we fabricated  $\text{SnFe}_2\text{O}_4$  based electrodes from the powders obtained by the microwave treatment of precursors ( $\text{FeCl}_3$  and  $\text{NaOH}$ ) along with  $\text{SnCl}_2$ , which interestingly gave rise to a microcube like morphology. Electrochemical analysis through cyclic voltammetry indicated a specific capacitance of the  $172 \text{ Fg}^{-1}$  for  $\text{SnFe}_2\text{O}_4$  which was almost three times higher in comparison to  $\text{Fe}_2\text{O}_3$  ( $70 \text{ Fg}^{-1}$ ) at a scan rate of  $5 \text{ mVs}^{-1}$ . Furthermore,  $\text{SnFe}_2\text{O}_4$  electrode worked as an excellent sensor for the nonenzymatic detection of  $\text{H}_2\text{O}_2$  and the calculated lower detection limit for  $\text{SnFe}_2\text{O}_4/\text{GCE}$  ( $41 \text{ nM}$ ) was three orders of magnitude lower than that of  $\text{Fe}_2\text{O}_3/\text{GCE}$  ( $0.3 \mu\text{M}$ ).

## 2. Experimental

### 2.1. Microwave assisted synthesis of $\text{SnFe}_2\text{O}_4$ microcubes and $\text{Fe}_2\text{O}_3$ nanorods

All chemicals used for synthesizing the samples were of analytical grade procured from Merck, used directly without any further purification. In a typical synthesis,  $100 \text{ mM FeCl}_3 \cdot 6\text{H}_2\text{O}$  dissolved in  $100 \text{ ml}$  of doubly distilled water was mixed with  $100 \text{ ml}$  solution of  $50 \text{ mM SnCl}_2 \cdot 2\text{H}_2\text{O}$  under continuous stirring at room temperature. Thereafter,  $\text{NaOH}$  flakes were directly added for increasing the pH of the solution to 13 and it was kept under constant magnetic stirring for 30 min. The final reaction mixture was placed inside a microwave oven and was reacted at a power of  $180 \text{ W}$  for 5 min. After microwave treatment, the solution was allowed to cool down to room temperature after which it was centrifuged by repeatedly washing the precipitates with excess distilled water and acetone. The washed precipitates were dried at  $60^\circ\text{C}$  for 12 h and were annealed at  $600^\circ\text{C}$  for 10 h in a muffle furnace. The final  $\text{SnFe}_2\text{O}_4$  sample obtained after annealing were brownish black colored powders.

$\text{Fe}_2\text{O}_3$  nanorod samples were prepared by following the same procedure as mentioned above without the addition of  $\text{SnCl}_2 \cdot 2\text{H}_2\text{O}$ . The precipitates of  $\text{Fe}_2\text{O}_3$  obtained after annealing at  $600^\circ\text{C}$  for 10 h were orange red in color.

### 2.2. Characterization

Structural properties of the prepared samples was analyzed using an X-ray diffractometer (XRD, Rigaku miniflex 600 XRD instrument) at the scan rate of  $2^\circ/\text{min}$  with a step size of  $0.02^\circ$  in the  $2\theta$  range  $10\text{--}80^\circ$ . Morphology and the compositional analysis were conducted using a field emission scanning electron microscope (FESEM, ZEISS) fitted with an energy dispersive X-ray spectrometer (EDS). Fourier transform infrared (FTIR, Bruker Alfa FTIR

spectrometer) spectra were recorded from  $400$  to  $4000 \text{ cm}^{-1}$  using KBr pellet. Thermal studies using both thermogravimetric analysis (TGA) as well as differential scanning calorimetry (DSC) were conducted on a TGA-DSC (DSC SDT Q600) system under nitrogen atmosphere by heating the samples from room temperature to  $800^\circ\text{C}$ . The specific surface area, pore volume and pore diameter of the samples were evaluated using the Brunauer-Emmett-Teller (BET) method from the nitrogen adsorption-desorption isotherms obtained using a BELSORP mini II instrument (BEL Japan Co., Ltd).

### 2.3. Preparation of supercapacitor electrodes and electrochemical characterization

Working electrode of the supercapacitor was fabricated using a slurry prepared by thoroughly mixing the active material ( $\text{Fe}_2\text{O}_3$  or  $\text{SnFe}_2\text{O}_4$ ), super P acetylene carbon black and polyvinylidene fluoride (PVDF) in the weight ratio of 7:2:1 with a few drops of N-methyl-2-pyrrolidone (NMP), which was brush coated on a pre-cleaned titanium foil (Alfa Aesar,  $0.25 \text{ mm}$  thickness and dimension  $5 \times 1 \text{ cm}$ ) and dried in a vacuum oven for 15 h at  $60^\circ\text{C}$ . The average mass of the active materials coated on the foil was  $0.35 \text{ mg}$ . Electrochemical studies were conducted on a Biologic SP-150 electrochemical workstation with three-electrode system using the sample coated titanium foil, platinum wire and  $\text{Ag}/\text{AgCl}$  as the working electrode, counter electrode and reference electrode, respectively. The electrochemical properties were characterized through cyclic voltammetry (CV, at different scan rates), galvanostatic charge-discharge (GSD) method and potentiometric electrochemical impedance spectroscopy (EIS) at a bias voltage of  $10 \text{ mV}$  in three different aqueous electrolytes viz.,  $1 \text{ M KOH}$ ,  $1 \text{ M NaOH}$  and  $1 \text{ M Na}_2\text{SO}_4$ .

### 2.4. Preparation of electrodes for nonenzymatic $\text{H}_2\text{O}_2$ sensor and its measurement

In a typical procedure, a glassy carbon electrode (GCE) was cleaned by polishing its surface with alumina ( $0.05 \mu\text{m}$ ) followed by electropolishing in  $0.5 \text{ M H}_2\text{SO}_4$  and sonicating in distilled water and ethanol for 5 s each. A homogeneous slurry was prepared by sonicating  $1 \text{ mg}$  of sample ( $\text{Fe}_2\text{O}_3$  or  $\text{SnFe}_2\text{O}_4$ ) in  $1 \text{ ml}$  of NMP for 1 h after which  $4 \mu\text{l}$  was drop casted using a micro pipette on the polished GCE surface ( $3 \text{ mm}$  diameter). The modified GCE was dried and used as the working electrode for sensing  $\text{H}_2\text{O}_2$  on a Biologic SP-150 electrochemical work station with three-electrode configuration against  $\text{Ag}/\text{AgCl}$  electrode. Pt wire was used as counter electrode in  $0.1 \text{ M}$  phosphate buffer saline (PBS) solution ( $\text{pH } 7$ ) as electrolyte.  $\text{H}_2\text{O}_2$  sensing performance was analyzed using CV at the scan rate of  $50 \text{ mVs}^{-1}$  and by chronopotentiometry at an applied current of  $0.4 \mu\text{A}$  in  $0.1 \text{ M}$  PBS solution.

## 3. Results and discussion

### 3.1. Structural, chemical and morphological characterization of $\text{Fe}_2\text{O}_3$ and $\text{SnFe}_2\text{O}_4$

XRD patterns of  $\text{Fe}_2\text{O}_3$  and  $\text{SnFe}_2\text{O}_4$  shown in Fig. 1a and 1b were analyzed and indexed using Panalytical Xpert high score plus software. XRD peaks of  $\text{Fe}_2\text{O}_3$  can be indexed to the rhombohedral structure of hematite (JCPDS card no. 01-089-0596) while the XRD pattern of  $\text{SnFe}_2\text{O}_4$  matched well with the phase pure monophasic inverse spinel structure (JCPDS card no. 01-071-0693) with a lattice constant of  $8.4 \text{ \AA}$  [26]. However, the XRD patterns of as-synthesized precipitates of  $\text{Fe}_2\text{O}_3$  as well as  $\text{SnFe}_2\text{O}_4$  before annealing at  $600^\circ\text{C}$  exhibited discrete phases (see Fig. S1, supplementary content). This indicates that Sn (in the form of  $\text{Sn}^{4+}$ ) ions enter the octahedral sites by replacing  $\text{Fe}^{3+}$  ions only
