ABSTRACT

Bacterial attachment and the subsequent formation of biofilm on surfaces of synthetic materials pose a 26 serious problem in both human healthcare and industrial applications. In recent decades, considerable 27 attention has been paid to developing antibacterial surfaces to reduce the extent of initial bacterial 28 attachment and thereby to prevent subsequent biofilm formation. Briefly, there are three main types 29 of antibacterial surfaces: bactericidal surfaces, bacteria-resistant surfaces, and bacteria-release surfaces. 30 The strategy adopted to develop each type of surface has inherent advantages and disadvantages; many 31 efforts have been focused on the development of novel antibacterial surfaces with dual functionality. In 32 this review, we highlight the recent progress made in the development of dual-function antibacterial sur- 33 faces for biomedical applications. These surfaces are based on the combination of two strategies into one 34 system, which can kill attached bacteria as well as resisting or releasing bacteria. Perspectives on future research directions for the design of dual-function antibacterial surfaces are also provided. 36

41 1. Introduction

 Bacterial attachment and the subsequent proliferation and colonization of bacteria on the surfaces of synthetic materials usu-44 ally result in the formation of a biofilm $[1-4]$. This bacterial biofilm poses a major problem in both human healthcare and industrial applications, including but not limited to public health settings, surgical equipment, biosensors, textiles, water purification 48 systems, and packaging $[5,6]$. For medical implants and devices, bacterial attachment adversely affects the functionality and limits the lifetime of devices, and bacterial infections represent a com- mon and substantial complication in the clinic, sometimes even 52 leading to death $[7,8]$. For food processing and packaging materials, the accumulation of bacteria has a serious impact on processing 54 efficiency, productivity, and food quality $[9]$. For marine equip- ment, microbial contamination on surfaces provides an easily accessible platform for other marine species to attach and prolifer- ate, leading to an increase in the cost of operation and maintenance [\[10\].](#page--1-0) To solve these problems, considerable efforts have been directed toward developing antibacterial surfaces that can greatly reduce the extent of initial bacterial attachment and thereby pre-vent subsequent biofilm formation [\[11–16\]](#page--1-0).

62 In recent decades, various antibacterial surfaces have been 63 designed, which can be divided into three categories based on

For example, bactericidal surfaces 71 can prevent the formation of viable biofilms, but these surfaces will 72 still be contaminated by remaining dead bacteria, which may 73 trigger immune responses or inflammation $[17]$. In addition, these 74 surfaces suffer the problems of ecotoxicity of biocides toward non- 75 targeted species and poor compatibility with mammalian cells. On 76 the other hand, bacteria-resistant surfaces or bacteria-release 77 surfaces can prevent or reduce the initial attachment of bacteria; 78 however, to date, no such surfaces can achieve 100% prevention 79 of bacterial attachment, inevitably becoming colonized by bacteria 80 that are not killed once they attach themselves to the surfaces. 81 Therefore, an ideal antibacterial surface that can perform the fol-
82 lowing functions is required: (i) first, prevent initial bacterial 83 attachment; (ii) subsequently, kill all bacteria that manage to over- 84 come this anti-adhesion barrier; and (iii) finally, remove dead bac- 85 teria. To achieve this goal, several groups have developed surfaces 86 by combining two strategies into one system. Over the past decade, 87 excellent reviews on the fabrication and application of antibacteri-
88 al surfaces with a single functionality have been published 89 $[18–22]$; however, to the best of our knowledge, few reviews on 90 dual-function antibacterial surfaces have been published [\[23\].](#page--1-0) 91

2 Q. Yu et al. / Acta Biomaterialia xxx (2015) xxx–xxx

 In this review, we first briefly introduce three main strategies for designing antibacterial surfaces with a single functionality: bactericidal surfaces, bacteria-resistant surfaces and bacteria- release surfaces. We then highlight recent developments in the creation of dual-function antibacterial surfaces based on the com- bination of two strategies (e.g., kill/resist or kill/release) into one system for biomedical applications. Finally, we conclude by pre- senting future research directions for developing dual-function antibacterial surfaces.

101 2. Basic strategies for designing antibacterial surfaces

102 2.1. Bactericidal surfaces

 Bactericidal surfaces refer to surfaces that are capable of killing bacteria. According to the killing mechanism, these surfaces can be divided into two main categories: contact-based bactericidal sur-faces and release-based bactericidal surfaces.

107 2.1.1. Contact-based bactericidal surfaces

 Contact-based bactericidal surfaces are surfaces that are coated with antibacterial agents by either covalent conjugation or physi- cal adsorption to kill adhering bacteria. The antibacterial agents used in this respect range from synthetic chemicals such as quater- nary ammonium compounds (QACs), polycations and various antibiotics to natural biomolecules such as chitosan, antimicrobial peptides (AMPs) and antimicrobial enzymes (AMEs). Herein, we introduce several typical examples.

 QACs with both long hydrophobic alkyl chains and positively charged quaternary ammonium groups have been demonstrated to show strong contact-killing activity toward both Gram-positive and Gram-negative bacteria. The ion exchange of QAC molecules 120 with Ca^{2+} and Mg²⁺ ions in the cytoplasmic membrane destabilizes the intracellular matrix of a bacterium; additionally, the hydropho- bic tail interdigitates into the hydrophobic bacterial membrane over the entire surface area of a bacterium, causing general pertur- bations in the cytoplasmic membrane and leakage of intracellular fluid containing essential molecules [\[24,25\]](#page--1-0). One typical QAC is the quaternary ammonium silane of 3-(trimethoxysilyl)-propy-127 Idimethyloctadecyl ammonium chloride (QAS, Fig. 1a), which can be easily immobilized onto OH-containing surfaces (such as

Fig. 1. Chemical structures of (a) 3-(trimethoxysilyl)-propyldimethyloctadecyl ammonium chloride (QAS), (b) quaternized poly(4-vinyl-N-alkylpyridinium bromide) (PVP), and (c) quaternized poly (2-(dimethylamino ethyl) methacrylate) (PDMAEMA).

silicone rubber [\[26\]](#page--1-0), cotton [\[27\],](#page--1-0) titanium [\[28\]](#page--1-0), silica particle 129 [\[29\]](#page--1-0), and cellulose [\[30\]\)](#page--1-0) by covalent bonds. In addition to QAS, 130 polymers with quaternary ammonium groups in their side chains 131 have also been explored as polymeric biocides. Quaternized 132 poly(4-vinyl-N-alkylpyridinium bromide) (PVP, Fig. 1b) [\[31,32\]](#page--1-0) 133 and quaternized poly(2-(dimethylamino ethyl) methacrylate) 134 (PDMAEMA, Fig. 1c) [\[33–35\]](#page--1-0) are two typical biocidal polymers. 135 For more information on antibacterial polymers, readers may refer 136 to other reviews [\[20,36,37\]](#page--1-0). 137

AMPs and AMEs represent natural alternatives to traditional 138 synthetic biocidal compounds for developing bactericidal coatings. 139 AMPs form an integral part of the innate immune system in most 140 organisms. The advantages of AMPs include limited immuno- 141 genicity, rapid bactericidal behavior, and less susceptibility to pro- 142 teolysis $[38]$. AMEs refer to a group of enzymes with abilities to 143 directly attack the microorganism, interfere with biofilm forma- 144 tion, and/or catalyze reactions which result in the production of 145 antimicrobial compounds [\[39\].](#page--1-0) According to the antibacterial 146 mechanism, they can be divided into three categories: proteolytic 147 enzymes, polysaccharide-degrading enzymes, and oxidative 148 enzymes [\[40\].](#page--1-0) AMPs and AMEs can be immobilized on supporting 149 surfaces either physically (e.g., via adsorption or layer-by-layer 150 assembly) or chemically (e.g., *via* covalent bonding) to fabricate 151 bactericidal coatings with a broad spectrum of antibacterial activ- 152 ity, high efficacy even at low concentrations, and lack of suscepti- 153 bility to bacterial resistance [\[39–41\].](#page--1-0) 154

2.1.2. Release-based bactericidal surfaces 155

Release-based bactericidal surfaces are surfaces within which 156 biocides are preloaded or embedded before being released slowly 157 into the environment to kill bacteria. The most widely used bio- 158 cides are silver nanoparticles (AgNPs) because of their strong and 159 broad-spectrum antibacterial characteristics [\[8,15,42–44\].](#page--1-0) The 160 main mechanism through which AgNPs exert their biocidal proper- 161 ties is through the release of $Ag⁺$ ions, which damage the bacterial 162 membrane as well as disrupt the function of bacterial enzymes 163 and/or nucleic acid groups in cellular protein and DNA $[45]$. There 164 are also several types of release-based bactericidal surfaces that 165 use antibiotics [\[46–48\]](#page--1-0) or nitrogen oxide [\[49–51\]](#page--1-0) as releasing bio- 166 cides to avoid bacterial infection. The same state of the state of

2.1.3. Dual-contact- and release-based bactericidal surfaces 168

Several bactericidal surfaces with two different biocides incor- 169 porated into one system operate through both contact-based and 170 release-based mechanisms. These surfaces are of particular inter- 171 est because they can minimize the selection and proliferation of 172 resistant strains, providing long-term antibacterial efficiency. For 173 example, a thin film coating composed of two distinct, layered 174 functional regions (i.e., a polyelectrolyte multilayer reservoir for 175 the loading and release of bactericidal AgNPs and a $SiO₂$ surface 176 cap with immobilized QAS, as shown in Fig. 2) was developed 177 [\[52\]](#page--1-0). Dual-function coatings of this type show high initial 178
