## ABSTRACT

The catalytic synthesis of cyclic carbonates via the cycloaddition of CO<sub>2</sub> to epoxides is a standard methodology for CO<sub>2</sub> fixation. For this purpose, chiral basket-handle porphyrin-Co complexes were devised, prepared, and fully characterized by nuclear magnetic resonance, mass spectrometry, Fourier transform infrared spectroscopy, ultraviolet-visible spectroscopy, and specific rotation. The proposed metalloporphyrin catalysts were synthesized with either 1,1'-bi-2-naphthol or L-phenylalanine, which have different chirality, and then applied to the coupling of propylene oxide and CO<sub>2</sub> for generating chiral cyclic carbonates with good enantioselectivity under extremely mild conditions in the presence of tetrabutyl ammonium chloride as a co-catalyst. The good enantioselectivity in the cycloaddition reaction is attributed to a synergistic interplay between the chiral porphyrin catalysts and the substrate. The mechanism and enantioselectivity of the asymmetric cycloaddition reaction is discussed.

## 1. Introduction

The transformation of CO<sub>2</sub> into useful organic compounds has been generating increasing interest from both economic and environmental points of view arising from the utilization of renewable resources and the reduction of greenhouse gases [1–6]. One of the most successful methodologies for CO<sub>2</sub> fixation is the catalytic synthesis of cyclic carbonates via the cycloaddition of CO<sub>2</sub> to epoxides [7–16]. These epoxides are highly useful products that have been widely used in organic synthesis and as pharmaceutical/fine chemical intermediates,

monomers, aprotic solvents, raw materials for plastics, and other such materials [17–23].

Biomimetic metalloporphyrins have been demonstrated to be effective catalysts for various organic reactions. Kruper et al. [24] have reported the coupling reaction of propylene oxide (PO) and CO<sub>2</sub> using a catalyst system composed of Cr(tetraphenylporphyrin [TPP])Cl with the co-catalyst 4-dimethylaminopyridine (DMAP), denoted generally as Cr(TPP)Cl/DMAP, to yield propylene carbonate (PC). In addition, Nguyen et al. [25] have developed the Co(TPP)X/DMAP catalyst system, and Srinivas et al. [26] have demonstrated the

Cu(II)porphyrin/DMAP catalyst system for conducting an equivalent coupling reaction. Recently, we have documented various porphyrin-Co/co-catalyst systems for the cycloaddition of CO<sub>2</sub> to epoxides [27–34].

Since the milestone work of Jacobsen et al. in 1997 [35] demonstrating the asymmetric ring-opening and kinetic resolution of aliphatic terminal epoxides, numerous examples of the synthesis of optically active cyclic carbonates by the catalytic kinetic resolution illustrated in Scheme 1 have been reported. Of these examples, chiral Schiff base Co complexes, particularly in the presence of nucleophilic reagents serving as co-catalysts, have been generally demonstrated to be the most effective catalysts for the coupling of CO<sub>2</sub> and epoxides [36–42]. In our previous work on CO<sub>2</sub> fixation, various types of bifunctional chiral catalysts were designed and prepared based on the chiral backbone of Co(III)salen complexes that can catalyze this asymmetric coupling reaction of CO<sub>2</sub> and epoxides to generate chiral cyclic carbonates under mild conditions [43–50,55]. However, the asymmetric synthesis of cyclic carbonates catalyzed by chiral metalloporphyrins has not been reported. Therefore, we designed and synthesized novel chiral basket-handle porphyrin-Co complexes with chiral picket-fence structures in the present work, and then successfully applied these complexes as catalysts for the asymmetric cycloaddition of CO<sub>2</sub> to epoxides.

## 2. Experimental

### 2.1. Preparation of chiral basket-handle porphyrin catalysts

The proposed chiral basket-handle porphyrin-Co complexes were fabricated according to the strategy depicted in Scheme 2. The precursor porphyrin **1** (meso-tetakis-(2-nitrophenyl) porphyrin); TNPP) was fabricated by the Lindsey method from pyrrole and 2-nitrobenzaldehyde, which was then reduced to porphyrin **2** (meso-tetakis-(2-aminophenyl) porphyrin); TAPP) according to previously reported methods [51,52]. Phenylalanine was then introduced to porphyrin **2** to generate chiral porphyrin **4**, which was linked by a second chiral group of (*R*)-2,2'-dihydroxy[1,1']binaphthalenyl-3,3'-dicarbaldehyde ((*R*)-**5**) to produce the target product of chiral basket-handle porphyrin **6a**. The metalloporphyrin complex **6b** was obtained by the reaction of porphyrin **6a** with cobalt acetate, and was then oxidized by air in the presence of acetic acid to form the chiral cobalttoporphyrin acetate catalyst **6c**. The chiral porphyrin catalysts **7a**, **7b**, and **7c** shown in Fig. 1 were fabricated by an equivalent method. The synthesis of all remaining precursors is described as follows.

**Scheme 2.** Synthetic routes for chiral porphyrin **4a** and **6a**.

#### 2.1.1. Synthesis of chiral porphyrin **3**

A solution of 1.46 g *N,N'*-dicyclohexyl carbodiimide (DCC; 7.1 mmol) in 80 mL of ethyl acetate was added into a round-bottomed flask containing *N*-*boc*-L-phenylalanine (1.70 g, 6.4 mmol) and TAPP (0.54 g, 0.8 mmol) dissolved in ethyl acetate (160 mL) at 25 °C. The mixture was then stirred for 24 h at room temperature, filtered, and washed with ethyl acetate. The filtrate was evaporated under vacuum, and the residue obtained was purified by column chromatography with CH<sub>2</sub>Cl<sub>2</sub>-MeOH (50:1) as the eluent. The pure porphyrin **3** product of tetrakis[2-(*N*-*tert*-butoxycarbonyl-L-phenylalaninoyl-amido)phenyl] was obtained with a 97.3% yield (1.28 g) [53].
