ABSTRACT

An immobilized $\text{Cu}_2\text{O}/\text{g-C}_3\text{N}_4$ heterojunction film was successfully made on an FTO substrate by electrophoretic deposition of $\text{g-C}_3\text{N}_4$ on a Cu_2O thin film. The photoelectrochemical (PEC) performance for water splitting by the $\text{Cu}_2\text{O}/\text{g-C}_3\text{N}_4$ film was better than pure $\text{g-C}_3\text{N}_4$ and pure Cu_2O film. Under -0.4 V external bias and visible light irradiation, the photocurrent density and PEC hydrogen evolution efficiency of the optimized $\text{Cu}_2\text{O}/\text{g-C}_3\text{N}_4$ film was -1.38 mA/cm^2 and 0.48 $\text{mL h}^{-1} \text{cm}^{-2}$, respectively. The enhanced PEC performance of $\text{Cu}_2\text{O}/\text{g-C}_3\text{N}_4$ was attributed to the synergistic effect of light coupling and a matching energy band structure between $\text{g-C}_3\text{N}_4$ and Cu_2O as well as the external bias.

1. Introduction

In the past several decades, photoelectrochemical (PEC) hydrogen evolution from water using semiconductors as photocatalyst has attracted extensive attention because it is a promising clean and renewable energy technology [1–5]. Among the various semiconductors, p-type cuprous oxide (Cu_2O) is one of the most promising visible light PEC materials for water splitting [6–8]. On the one hand, Cu_2O gives a higher

photoconversion efficiency with a conduction band (CB) of -1.4 eV versus NHE and a direct band gap of 2.0 – 2.4 eV [9,10]. On the other hand, the photocurrent and light-to-hydrogen conversion efficiency of Cu_2O can be as high as -14.8 mA/cm^2 and 18.7% , respectively, in theory [11]. However, the reported photoconversion efficiency of Cu_2O is far below the theoretical value [12,13]. Furthermore, pure Cu_2O suffers from inadequate stability in the presence of visible light [12,14]. Therefore, attention was focused on improving the PEC performance and

stability of Cu₂O [15,16].

It is well known that graphitic carbon nitride (g-C₃N₄) or composites based on g-C₃N₄ are promising visible light photocatalysts for the PEC or photocatalytic (PC) hydrogen evolution due to their low band gap energy of 2.7 eV, and their metal-free semiconductivity, nontoxicity, and natural abundance [17–24]. In addition, the CB and VB positions of g-C₃N₄ are –1.1 and 1.6 eV vs. NHE, respectively [25,26], which exactly matches the band potentials of Cu₂O [9,10]. Many works have reported that the photocatalytic activity of a Cu₂O/g-C₃N₄ heterojunction photocatalyst was greatly improved compared to pure Cu₂O and pure C₃N₄ [27–32]. For example, our study showed that a g-C₃N₄/Cu₂O composite powder displayed an enhanced photocatalytic performance compared to pure g-C₃N₄ and pure Cu₂O because of the better separation of photogenerated charges (electron-hole pairs) in the two semiconductors [32]. However, reported Cu₂O/g-C₃N₄ composites are almost all powder photocatalysts, which are difficult to separate from liquid systems. Furthermore, it is necessary to add sacrificial agent as electron donors and deposit the co-catalyst on Cu₂O/g-C₃N₄ in the photocatalytic process.

It will broaden the application of g-C₃N₄/Cu₂O composites as visible light photocatalysts to immobilize g-C₃N₄ on a Cu₂O film based on the FTO substrate because the PEC performance can be improved by the reduction of electron-hole recombination and the photoelectrode can be easily recycled and reused. In this study, we fabricated a Cu₂O/g-C₃N₄ heterojunction film on an FTO substrate by an electrochemical deposition method. The Cu₂O/g-C₃N₄ film showed excellent activity and reusability for visible light PEC water splitting.

2. Experimental

2.1. Materials and synthesis

The Cu₂O films on the FTO substrate were grown by the electrochemical deposition method in a three-electrode cell using FTO glass (3.5 × 2 cm²), Pt plate and Ag/Cl (SAE) as the working, counter and reference electrodes, respectively [33]. A solution of 0.4 mol/L CuSO₄ and 3.0 mol/L lactic acid was applied as the electrolyte. The electrolyte was adjusted to pH = 10.0 with 5.0 mol/L NaOH aqueous solution. The electrochemical deposition potential was –0.8 V_{SAE} and deposition time was 100 s. The samples obtained were cleaned with deionized water and dried overnight in vacuum.

The g-C₃N₄ nanoparticles were fabricated by a general sol-gel method reported in our previous reports [32,33]. The g-C₃N₄ nanoparticles were deposited on the Cu₂O film on the FTO substrate by an electrophoretic deposition process [34]. Briefly, g-C₃N₄ nanoparticles loaded on the Cu₂O films of the FTO substrate were obtained in a two-electrode cell using a deposition potential of 50 V, and the FTO substrate with the Cu₂O film and Pt plate were used as the cathode and anode, respectively. The two electrodes were immersed in the electrolyte and then 40 mg g-C₃N₄ and 10 mg iodine powder were added to 50 mL acetone and sonicated for 20 min. The content of g-C₃N₄ in the Cu₂O/g-C₃N₄ heterojunction film was controlled

by the deposition time. In the process, iodine in the solution reacts with acetone and generated H⁺, which made the g-C₃N₄ particles positively charged. Four Cu₂O/g-C₃N₄ samples were prepared by varying the deposition time as 5, 10, 15 and 20 s, and are denoted as Cu₂O/g-C₃N₄-5, Cu₂O/g-C₃N₄-10, Cu₂O/g-C₃N₄-15 and Cu₂O/g-C₃N₄-20, respectively. Pure Cu₂O and g-C₃N₄ films were also fabricated for comparison. The deposition time of pure g-C₃N₄ on FTO was 15 s. Finally, the obtained samples were dried in vacuum at 80 °C.

2.2. Characterization

The surface morphology of the samples was viewed on a field emission scanning electron microscope (FESEM, LEO 1530VP, Germany) and a model JEOL-2010 transmission electron microscope (TEM, Japan) with an operation voltage of 200 kV. The element contents of the samples were analyzed by energy dispersive X-ray spectroscopy (EDX, JEM-2100). The crystal structure of the samples was determined using a Model D/max 2500v/pc X-ray diffractometer (XRD, Rigaku, Japan). Diffuse reflectance absorption spectra were recorded using an ultraviolet-visible (UV-vis) spectrometer (U3010, Hitachi).

2.3. Evaluation

PEC tests were performed with a three-electrode cell described in our previous report [33]. The PEC experiments for hydrogen and oxygen production were completed in a 150 mL temperature controlled three-electrode sealed cell (NBeT, Beijing) at an applied potential of –0.4 V under visible light (100 mW/cm²) illumination. The light was from a 300W Xe arc lamp equipped with an ultraviolet cutoff filter to provide visible light with $\lambda \geq 400$ nm (PLS-SXE300UV Xe lamp, 100 mW/cm²). A 0.1 mol/L NaNO₃ solution was used as supporting electrolyte, Ag/AgCl as reference electrode, and the Cu₂O/g-C₃N₄ film on the FTO substrate (2.0 × 2.0 cm²) as working electrode and Pt wire as counter electrode. A gas sample of 100 μ L was withdrawn from the cell headspace every 1 h with a glass syringe and analyzed using a gas chromatograph (GC-14C, Shimadzu, Japan, TCD) equipped with a 5 Å molecular sieve column and high purity nitrogen as carrier gas.

3. Results and discussion

3.1. Structure and composition

Two distinct diffraction peaks was observed in the XRD pattern of the pure Cu₂O film on the FTO substrate (Fig. 1). The stronger peak located at $2\theta = 36.52^\circ$ was due to the (111) plane of Cu₂O, and the other one located at $2\theta = 42.44^\circ$ was attributed to the (200) plane of Cu₂O [33,35]. For the pure g-C₃N₄ film on the FTO substrate, one characteristic peak at $2\theta = 27.53^\circ$, corresponding to the interlayer stacker structural packing, was observed. The weak diffraction peak at $2\theta = 13.12^\circ$ for g-C₃N₄ reported in our previous work [32] was not observed. The possible reason was the appearance of the strong characteristic peak at 37.70° of the FTO substrate. Also shown in Fig.
