## ABSTRACT

Photochemical production of H<sub>2</sub>O<sub>2</sub> through O<sub>2</sub> reduction has been proposed as an alternative method of solar energy storage. A carbon nitride (CN) photocatalyst was selected for this purpose. The incorporation of KPF<sub>6</sub> into the CN structure greatly enhanced the apparent quantum yield (AQY) of H<sub>2</sub>O<sub>2</sub> production in the UV and visible light region. The AQY of KPF<sub>6</sub>-modified CN was measured to be 35.9% and 24.3% under monochromatic irradiation at 370 and 420 nm, respectively, which are 8.3 and 26.1 times higher than for bare CN. The KPF<sub>6</sub>-enhanced activity is ascribed to several factors including (i) enhanced absorption of UV and visible light, (ii) higher charge carrier density, (iii) retarded radiative recombination of charge pairs, (iv) highly selective two-electron transfer to O<sub>2</sub>, and (v) hindered photodecomposition of in-situ generated H<sub>2</sub>O<sub>2</sub>. The markedly high selectivity of KPF<sub>6</sub>-modified CN toward the two-electron reduction of O<sub>2</sub> (leading to H<sub>2</sub>O<sub>2</sub>) was demonstrated in comparison with other photoreductive conversions such as the reduction of polyoxometalate (POM → POM<sup>−</sup>), hexavalent chromium (Cr<sup>VI</sup> → Cr<sup>III</sup>), CCl<sub>4</sub> (dechlorination), and protons (H<sub>2</sub> production). This study developed a simple method of efficient production of H<sub>2</sub>O<sub>2</sub> using visible light, which could be utilized for a variety of applications that employ H<sub>2</sub>O<sub>2</sub> as a solar fuel or a green oxidant.

## 1. Introduction

Hydrogen peroxide (H<sub>2</sub>O<sub>2</sub>) is a clean oxidant that is widely used for pulp bleaching, deinking of recycled paper, chemical synthesis (e.g., the production of propylene oxide), water treatment, food industry processes, etc. [1–4]. H<sub>2</sub>O<sub>2</sub> is commonly produced by the anthraquinone method, which consists of steps of (i) hydrogenation of 2-alkylanthraquinone (AQ) to anthrahydroquinone (AHQ), (ii) reoxidation of AHQ to AQ with air with concurrent production of H<sub>2</sub>O<sub>2</sub>, (iii) H<sub>2</sub>O<sub>2</sub> extraction to aqueous solution, and (iv) purification. The yield of H<sub>2</sub>O<sub>2</sub> is high, but the process needs organic solvents, high energy input, and H<sub>2</sub> gas, which are costly and not environmentally friendly [5]. Direct synthesis of H<sub>2</sub>O<sub>2</sub> from the reaction of hydrogen and oxygen gas on metal catalysts such as Pd and Au–Pd alloy has high activity and selectivity, but it could be dangerous and demands precious metals [6,7].

Photocatalytic production of H<sub>2</sub>O<sub>2</sub> is a safe and environmentally benign method since it requires water, oxygen, and light only. The in situ formation of H<sub>2</sub>O<sub>2</sub> as an intermediate during various photo-

catalytic processes has frequently been observed, but the production of H<sub>2</sub>O<sub>2</sub> as a final product has recently been in the spotlight [1,8]. H<sub>2</sub>O<sub>2</sub> can be generated by sequential two-electron transfer (first step: O<sub>2</sub> + e<sup>−</sup> + H<sup>+</sup> → HO<sub>2</sub>; second step: HO<sub>2</sub> + e<sup>−</sup> + H<sup>+</sup> → H<sub>2</sub>O<sub>2</sub>) or concerted two-electron transfer (O<sub>2</sub> + 2H<sup>+</sup> + 2e<sup>−</sup> → H<sub>2</sub>O<sub>2</sub>). Proton-coupled electron transfer (PCET) and the stabilization of in situ generated H<sub>2</sub>O<sub>2</sub> are desired to achieve high production efficiency. Some strategies for optimizing photocatalytic H<sub>2</sub>O<sub>2</sub> production can be classified according to the modification methods: (i) metal co-catalysts loading (AgAu/TiO<sub>2</sub>, Cu/TiO<sub>2</sub>, Au/carbon nitride (CN), etc.) [9–12], (ii) hybridization with carbon nanomaterials (graphene/TiO<sub>2</sub>, graphene/CdS, graphene/pyromellitic diimide (PDI)-modified CN, etc.) [1,13,14], (iii) surface passivation (fluoride/TiO<sub>2</sub>, phosphate/TiO<sub>2</sub>, etc.) [1,8,15], and (iv) chemical structural modification to control electronic and surface properties (PDI-modified CN, biphenyl diimide (BDI)-modified CN, CN with N-rich or C-vacancies, heteroelements-incorporated CN, etc.) [16–20]. For example, tri-s-triazine moieties on CN polymeric frameworks can facilitate photoinduced electron transfer to O<sub>2</sub> to produce H<sub>2</sub>O<sub>2</sub>, and the incorporation of earth-abundant heteroelements (K, P, and O) into the CN matrix significantly increases the production of H<sub>2</sub>O<sub>2</sub> as a result of the formation of charge trapping sites and phosphate species over the surface [20]. In this study, the highest quan-

tum yield (QY) for the production of  $\text{H}_2\text{O}_2$  was achieved over the UV and visible light region by simple co-condensation of melamine and potassium hexafluorophosphate ( $\text{KPF}_6$ ). Not only the incorporation of  $\text{K}^+$  into the nitride pots of the CN framework but also the insertion of  $\text{PF}_6^-$  into the CN layers increased UV and visible light absorption and selectively promoted two-electron transfer to  $\text{O}_2$  to yield  $\text{H}_2\text{O}_2$  under irradiation.

## 2. Experimental

### 2.1. Chemicals and catalyst preparation

The synthesis of bare CN was done following the reported method with a slight change of calcination temperature [20]. A quantity of 4 g of melamine (99%, Aldrich) was put into a porcelain cup with a cap and calcined at  $520^\circ\text{C}$  for 4 h with a ramp rate of  $2.2^\circ\text{C}/\text{min}$ . Although the calcination temperature was not sufficiently high to transform melamine completely into a graphitic carbon nitride structure, it was chosen for this study because bare and modified CN samples calcined at this temperature showed the best activity in  $\text{H}_2\text{O}_2$  production. After the heating process, the resulting product was gently ground and ultrasonicated for 3 h in an aqueous suspension (1 g/L). Then the powder was filtered, washed, and dried for further tests.  $\text{KPF}_6$ -modified CN ( $\text{KPF}_6\text{-CN}$ ) was synthesized by a similar process of thermal polymerization. Different amounts (3, 5, 10, 15, 20 mmol) of potassium hexafluorophosphate ( $\text{KPF}_6$ , 98%, Aldrich) were mixed with melamine and ground together before the calcination process. The resulting samples were named according to the dopant amount as  $\text{KPF}_6\text{-CN}_3$ ,  $\text{KPF}_6\text{-CN}_5$ ,  $\text{KPF}_6\text{-CN}_{10}$ ,  $\text{KPF}_6\text{-CN}_{15}$ , and  $\text{KPF}_6\text{-CN}_{20}$ , respectively.

Fig. 1. XRD spectra of (a) bare CN calcined at various temperature and (b)  $\text{KPF}_6$ -modified CN calcined at  $520^\circ\text{C}$  with varying  $\text{KPF}_6$  content.

Fig. 2. (a) Deconvoluted XPS core-level spectra of C1s and K2p for bare CN and  $\text{KPF}_6\text{-CN}_{15}$ , (b)  $^{31}\text{P}$  MAS NMR spectra, and (c)  $^{19}\text{F}$  MAS NMR spectra for bare CN,  $\text{KPF}_6\text{-CN}_{15}$ , the physical mixture of  $\text{KPF}_6$  and bare CN, and pure  $\text{KPF}_6$ . The NMR spectra of the samples ( $\text{KPF}_6\text{-CN}$ ,  $\text{KPF}_6 + \text{CN}$ , and  $\text{KPF}_6$ ) were normalized for facile comparison.

Unless otherwise mentioned,  $\text{KPF}_6\text{-CN}$  represents  $\text{KPF}_6\text{-CN}_{15}$ , which exhibited the optimal activity. To investigate the effect of different dopants as controls, 15 mmol of  $\text{KNO}_3$  (99.99%, Aldrich),  $\text{H}_3\text{PO}_4$  (85 wt%, Aldrich),  $\text{NH}_4\text{F}$  (98%, Aldrich),  $\text{KF}$  (99+%, Aldrich),  $\text{K}_2\text{HPO}_4$  (98%, Aldrich), or  $\text{NH}_4\text{PF}_6$  (95+%, Aldrich) was mixed with melamine (instead of  $\text{KPF}_6$ ) to prepare control samples of  $\text{K}_2\text{CN}$ ,  $\text{P}_2\text{CN}$ ,  $\text{F}_2\text{CN}$ ,  $\text{KF}_2\text{CN}$ ,  $\text{KP}_2\text{CN}$ , and  $\text{PF}_2\text{CN}$ , respectively.

### 2.2. Photocatalytic activity tests

For the reductive conversion of  $\text{O}_2$  to  $\text{H}_2\text{O}_2$ , a proper amount of catalyst (0.5 g/L) was dispersed in a mixed solution of deionized water and ethanol (10 vol%). The solution was then sonicated for
