Keywords: Fischer-Tropsch synthesis Lower olefins  $\chi$ -Fe<sub>5</sub>C<sub>2</sub> catalyst Promoters Theoretical and experimental insights

## ABSTRACT

As a sustainable and short-flow process, iron-catalyzed direct conversion of CO-rich syngas to lower olefins without intermediate steps, i.e., Fischer-Tropsch-to-Olefins (FTO), has received increasing attention. However, its fundamental understanding is usually limited by the complex crystal phase composition in addition to the interferences of the promoter effects and inevitable catalyst deactivation. Until recently, the combination of multiple in-situ/ex-situ characterizations and theoretical studies has evidenced Hägg iron carbide ( $\chi$ -Fe<sub>5</sub>C<sub>2</sub>) as the dominant active phase of iron-based Fischer–Tropsch catalysts. This perspective attempts to review and discuss some recent progresses on the nature of  $\chi$ -Fe<sub>5</sub>C<sub>2</sub> catalyst and the crucial effects of promoters on the FTO performance from theoretical and experimental viewpoints, aiming to provide new insights into the rational design of iron-based FTO catalysts.

1

#### 1. Introduction

2 Development of catalysts for direct conversion of CO-rich syngas derived from coal and biomass to lower olefins  $(C_2^{=}-C_4^{=})$  is 3 of burgeoning scientific and industrial interest [1–4]. Iron catalysts 4 appear to be the best candidate for this purpose, not only because 5 6 of the lower cost, higher availability, higher selectivity to  $C_2^{=}-C_4^{=}$ and higher resistance to contaminants from a commercial stand-7 point, but also because of the higher water-gas shift activity to 8 promote the CO reactant reacting with the formed H<sub>2</sub>O for the 9 generation of H<sub>2</sub> in addition to CO<sub>2</sub> and thus to enable the in-situ 10 11 adjustment of  $H_2/CO$  ratio [5–7]. To steer the product selectivity to light hydrocarbons, the Fischer-Tropsch-to-Olefins (FTO) process is 12 generally carried out at relatively high temperature, which could 13 make full use of the iron-based catalysts with the lower CH<sub>4</sub> 14 selectivity compared to other commonly used Fischer-Tropsch cat-15 16 alysts, e.g., Ru and Co [7,8]. Recently, a growing number of studies are conducted to understand the iron-based FTO process with 17 the aim to develop highly efficient iron-based catalysts for the 18 reaction [5-17]. There is an consensus that supported Fe catalysts, 19 20 especially for using  $\alpha$ -Al<sub>2</sub>O<sub>3</sub> and nanostructured carbon materials 21 as the supports, are more suitable for practical applications than unsupported (also referred to as bulk) Fe catalysts, owing to the 22

[5,7,12,18-20]. The FTO on iron-based catalysts is known to be a structure-25 sensitive reaction, meaning that the catalytic performance strongly 26 depends on the particle size of the active phase [21-24]. However, 27 limited direct information exists on the effects of the iron particle 28 size on the catalytic performance, mainly because the iron phase 29 composition highly depends on the iron particle sizes, promoters 30 and supports, and the reported catalysts generally undergo deac-31 tivation [5,13]. During the pretreatment steps of the iron-based 32 catalysts and real FTO conditions, the carburization process in-33 evitably leads to the formation of a series of metallic Fe, iron 34 carbides (e.g.,  $\varepsilon$ -Fe<sub>2</sub>C,  $\theta$ -Fe<sub>3</sub>C and  $\chi$ -Fe<sub>5</sub>C<sub>2</sub>) and iron oxides (e.g., 35  $\alpha$ -Fe<sub>2</sub>O<sub>3</sub>,  $\gamma$ -Fe<sub>2</sub>O<sub>3</sub>, Fe<sub>3</sub>O<sub>4</sub> and FeO), significantly increasing the dif-36 ficulty and complexity in the discrimination of iron active phases 37 [25,26]. Until recently, Hägg iron carbide ( $\chi$ -Fe<sub>5</sub>C<sub>2</sub>) is discrimi-38 nated as the dominant active phase by the integrated theoretical 39 studies with multiple advanced in-situ/ex-situ characterizations 40 [27]. 41

In this perspective, some recent and theoretical experimen-42 tal progresses on the nature of  $\chi$ -Fe<sub>5</sub>C<sub>2</sub> catalyst and the cru-43 cial effects of promoters on the FTO performance were re-44 viewed and discussed in detail. Finally, the conclusions and 45 prospects were provided. It is worth noting that for some other 46 critical issues on the fundamentals of the development, ap-47 plication and deactivation of iron-based Fischer-Tropsch cata-48 lyst, the readers could refer to several comprehensive reviews 49 [1,25,28,29]. 50

(c) Percentage of the exposed crystal facets of  $\chi$ -Fe<sub>5</sub>C<sub>2</sub> crystallite on the basis of Wulff construction, where the data originate from Ref. [32]. (d) Side views of  $\chi$ -Fe<sub>5</sub>C<sub>2</sub> (510), (021), (001) and (010) surfaces, where the blue and gray spheres correspond to the Fe and C atoms, respectively.

#### 51 2. The nature of $\chi$ -Fe<sub>5</sub>C<sub>2</sub> catalyst

#### 52 2.1. Theoretical studies

 $\chi$ -Fe<sub>5</sub>C<sub>2</sub> has a monoclinic unit cell with space group C2/c, 53 where the carbon atoms, occupying the interstice between close-54 55 packed iron atoms, are located in the trigonal-prismatic inter-56 stices (Fig. 1a) [30,31]. Density functional theory (DFT) calculations were carried out to calculate the surface energies of repre-57 sentative 11 facets shown in Fig. 1(b). Fig. 1(c) presents the per-58 centage of the exposed crystal facets of  $\chi$ -Fe<sub>5</sub>C<sub>2</sub> crystallite based 59 60 on Wulff construction [32]. It was revealed that some high Miller index surfaces, e.g.,  $\chi$ -Fe<sub>5</sub>C<sub>2</sub> (510) and (021), exhibit lower sur-61 face energies and thus are thermodynamically more stable, lead-62 63 ing to larger contribution to the total surface area of  $\chi$ -Fe<sub>5</sub>C<sub>2</sub>. These high Miller index surfaces were experimentally observed 64 65 by HRTEM [30,33–37]. In addition, they are terrace-like, whereas the low Miller index surfaces, e.g.,  $\chi$ -Fe<sub>5</sub>C<sub>2</sub> (010) and (001), are 66 generally step-like (Fig. 1d). These unique features are very dif-67 ferent from those of monometallic Fischer-Tropsch catalysts (e.g., 68 69 Ru, Co and Fe), i.e., the low Miller index surfaces exposed mostly, 70 whilst the high Miller index surfaces being thermodynamically less 71 stable.

There has been an increasing interest on fundamental un-72 73 derstanding of the Fischer-Tropsch synthesis mechanism on this unique  $\chi$ -Fe<sub>5</sub>C<sub>2</sub> catalyst. CO activation is a key step in the initi-74 75 ation of the Fischer-Tropsch synthesis process, and its preferred 76 pathway is used to compare the activity of the catalysts. Gener-77 ally, the direct CO dissociation pathway corresponds to higher activity in comparison with the H-assisted CO dissociation [38]. Table 78 1 gives a comparison of the preferred pathways for the CO dis-79 sociation among different  $\chi$ -Fe<sub>5</sub>C<sub>2</sub> surfaces [32,39–43]. Obviously, 80 the direct CO dissociation is the preferred CO activation pathway 81 for the terrace-like  $\chi$ -Fe<sub>5</sub>C<sub>2</sub> (510) surface, while the H-assisted CO 82 dissociation for the step-like  $\chi$ -Fe<sub>5</sub>C<sub>2</sub> (010) and (001) surfaces. Ad-83 84 ditionally, the overall barrier of CO activation on the terrace-like  $\chi$ -Fe<sub>5</sub>C<sub>2</sub> (510) surface is lower than that on the step-like surfaces. 85 These indicate the terrace-like  $\chi$ -Fe<sub>5</sub>C<sub>2</sub> (510) surface with higher 86 activity. It could be reasonably deduced that the terrace-like sur-87

<sup>d</sup> The surface carbon hydrogenation being more active than CO activation.

faces of  $\chi$ -Fe<sub>5</sub>C<sub>2</sub> act as the active sites for the FTO. This finding is 88 different from the trend for the monometallic Fischer-Tropsch cat-89 alysts that the direct CO dissociation prefers to occur at the step 90 sites [44–46]. Moreover, it can be also shown in Table 1 that the presence of C-vacancy on the step-like surfaces facilitates the occurrence of CO dissociation.

In addition to the activity, the product selectivity of  $\chi$ -Fe<sub>5</sub>C<sub>2</sub> Fischer-Tropsch catalyst is also an important issue for upgrading Fischer-Tropsch products to meet various end-use applications. 96 The pioneering work of Hu and coworkers has used the effec-97 tive barrier difference between  $CH_4$  formation and  $C_1-C_1$  coupling 98  $(\Delta E_{\rm eff})$  as a descriptor to compare the product selectivity for dif-99 ferent Fischer-Tropsch catalysts [47,48]. According to this defini-100 tion, the higher  $\Delta E_{eff}$  represents the higher  $C_{2+}$  selectivity and 101 the lower CH<sub>4</sub> selectivity. Table 2 gives a comparison of  $\Delta E_{\rm eff}$ 102
