**ABSTRACT:** The Development of innovative treatment technology for HCN at low temperatures is vital for the control of HCN pollution. Here, a copper manganese oxide (Cu-Mn-O) catalyst was prepared for the decomposition of HCN at temperatures from 80 to 200 °C. The results showed that the Cu-Mn-O catalyst exhibited excellent catalytic performance for HCN conversion. X-ray photoelectron spectroscopy analysis revealed that Mn<sup>3+</sup> manifested highly catalytic activity and was largely responsible for HCN decomposition. The N-contained products of HCN contained NH<sub>3</sub>, NO/NO<sub>2</sub>, N<sub>2</sub>O, and N<sub>2</sub>, thereby suggesting the concurrent catalytic oxidation and hydrolysis during HCN decomposition on the catalyst. The catalytic oxidation mechanism characterized by *in situ* diffuse reflectance infrared Fourier transform manifested that four N-contained intermediates (i.e., -CN, -NH<sub>2</sub>, =NH and -NCO) were produced; subsequent the oxidation of these intermediates resulted in the formation of final product and/or oxidative species NO<sup>+</sup>. The reaction of NO<sup>+</sup> with the N-contained intermediates also generated the final conversion products. Catalytic intermediate formamide plays a critical role in the hydrolysis of HCN, and its hydrolysis leads to the formation of NH<sub>3</sub>. Multiple cycle experiments demonstrate the long-term stability of the Cu-Mn-O catalyst. These results indicate that catalytic decomposition of HCN based on the Cu-Mn-O catalyst at low temperatures may be an efficient approach for the treatment of tail gases containing HCN.
