### Abstract

Plasma electrochemistry is an emerging technique for nanomaterial synthesis. The present study reports the preparation of yttrium oxide nanoparticles via a simple, environmentally benign, microplasma-assisted process operated in pin-to-liquid configuration under ambient atmospheric conditions using yttrium nitrate aqueous solution as the precursor. The plasma-liquid interaction was monitored *in-situ* by optical emission spectroscopy. The morphology, structure and chemical composition of the obtained products were examined by complementary analytical methods. It was demonstrated that high purity crystalline Y<sub>2</sub>O<sub>3</sub> nanoparticles with adjustable sizes can be fabricated via a two-step method: plasma electrodeposition of yttrium hydroxide followed by heat-treatment at various temperatures. A microplasma array design was proposed for the process upscaling towards industrial level production. Moreover, possible mechanisms for plasma-assisted yttrium hydroxide precipitation were discussed by correlating optical emission spectroscopic studies, plasma kinetic analysis and the precipitation equilibrium. As a proof-of-concept, this process offers a facile, environmental friendly and scalable route for rare-earth oxide nanomaterial synthesis.

**Keywords:** microplasma; micro reactor; electrochemistry; plasma-liquid interaction; Y<sub>2</sub>O<sub>3</sub> nanoparticles

### Introduction

The synthesis of yttrium oxide (Y<sub>2</sub>O<sub>3</sub>) nanostructures has been of long standing interest, motivated primarily by their fascinating properties such as high refractory performance (melting point ~2450°C), good thermal conductivity (33 W·m<sup>-1</sup>·K<sup>-1</sup>), superior chemical stability as well as excellent mechanical properties (Aghazadeh et al., 2010; Lakshminarasappa et al., 2014). Nanoscale Y<sub>2</sub>O<sub>3</sub> powders have been widely used in many areas especially where high performance or high temperature are required, such as nuclear ceramics (Verhiest et al., 2009),
