## 10 11 12 **Abstract**

13 The reduction of the activation or kinetic overpotential for the oxygen evolution and  
14 reduction reactions (OER/ORR) is of central significance to optimize conversion efficiency of  
15 polymer electrolyte water electrolysis and fuel cells (PEWE/PEFC). In both cases increasing  
16 temperature seems to be an option. In this work, similarities and differences of temperature-  
17 dependence of the kinetic overpotential of the oxygen evolution and reduction reactions are  
18 investigated. While both overpotentials decrease with temperature, only in PEWE a  
19 significant cell performance gain is obtained at relevant current densities due to the  
20 decreasing reversible thermodynamic cell voltage with temperature. Furthermore, for both  
21 reactions, the corresponding activation energies at constant overpotentials and constant cell  
22 voltages are determined according to the Butler-Volmer equation and transition state theory.  
23 At constant overpotentials a similar decrease in the activation energy from equilibrium  
24 conditions (approx. 67 kJ/mol) to an overpotential of about 0.3 V (approx. 40 kJ/mol) is
