## ABSTRACT

Mercury removal in wet flue gas desulfurization (WFGD) systems has been widely known to be effective, but removal efficiency is highly susceptible to calcium sulfite ( $\text{CaSO}_3$ ), the main byproduct of WFGD systems. Though the influence of  $\text{CaSO}_3$  on  $\text{Hg}^0$  re-emission has been studied, systematic studies directly devoted to removal are rare. In this study, the effects of  $\text{CaSO}_3$  on  $\text{Hg}^0$  removal efficiency were investigated using a  $\text{H}_2\text{O}_2/\text{Fe}^{3+}$  solution as an oxidizing agent. In addition, this experiment was designed to study the influence of operational conditions (temperature and pH), anions ( $\text{Cl}^-$  and  $\text{NO}_3^-$ ), and combustion flue gas components ( $\text{SO}_2$  and NO) in WFGD systems on  $\text{Hg}^0$  removal efficiency using a  $\text{H}_2\text{O}_2/\text{Fe}^{3+}$  solution with and without  $\text{CaSO}_3$ . For this experiment, three groups were chosen: 1) the absence of  $\text{CaSO}_3$ , 2) a 0.015%  $\text{CaSO}_3$  solution, and 3) a 0.075%  $\text{CaSO}_3$  solution. After the investigation of  $\text{Hg}^0$  removal efficiency with single flue gas component, the influence of co-existence gases ( $\text{SO}_2$ , NO,  $\text{Hg}^0$ ) on the simultaneous removal was studied. Results indicated that  $\text{CaSO}_3$  had adverse effects on  $\text{Hg}^0$  removal. For simultaneous removal, the co-existence of  $\text{SO}_2$  and NO was favorable for  $\text{Hg}^0$  removal. Also,  $\text{Cl}^-$  had a desirable effect on NO removal. This study provides new insights into the simultaneous removal of  $\text{SO}_2$ , NO, and  $\text{Hg}^0$  in WFGD systems.

## 1. Introduction

Mercury, increasingly known as an extremely toxic pollutant, is derived from the natural environment and human activities. Coal-fired power plants are a primary source of anthropogenic mercury discharge [1]. This has become a serious problem in China, where coal-fired power plants are common [2]. Symptoms of prolonged or acute exposure to mercury include: tremors, emotional changes, insomnia, neuromuscular changes, headaches, disturbance in sensations, changes in nerve responses and other negative symptoms [3]. In order to minimize the danger from mercury to inhabitable environment, mercury-specific environmental laws have been instituted in recent years in accordance with the Clean Air Act [4].

Mercury can be found in three forms in coal-fired flue gas: elemental mercury ( $\text{Hg}^0$ ), oxidized mercury ( $\text{Hg}^{2+}$ ), and particle bound mercury ( $\text{Hg}^p$ ) [5]. Oxidized mercury can be removed by wet flue gas desulfurization (WFGD) systems due to its water-solubility, and research has confirmed that the absorbing efficiency can be as high as 80–90% [6]. Particle bound mercury can be bound using an electrostatic precipitator [7]. Elemental mercury is insoluble in water and highly volatilizable, and hence, difficult to remove. Therefore, the key to  $\text{Hg}^0$  removal from flue gas is its oxidization to  $\text{Hg}^{2+}$  that occurs when the flue gas is injected into the adsorbing solution. After that,  $\text{Hg}^{2+}$  is absorbed into wet flue gas desulfurization devices (WFGD) [8]. According to a review of the literature pertaining to elemental mercury abatement methods, there are two main methods to purify  $\text{Hg}^0$  from flue gas: adsorption and oxidation [8,9]. Adsorbents used in the adsorption process include activated carbon [10], modified activated carbon [11], fly ash [12], modified fly ash [13], metal oxides [14], magnetic biochar [15], and calcium-based materials [16]. However, the cost of purification using these materials is high [7]. In recent years, numerous oxidation technologies have been developed including catalytic oxidation [17,18], advanced oxidation [19], and traditional chemical oxidation technologies [20].

Among these methods, the Fenton reaction based methods have generally been considered to be not only highly efficient, but also cost-effective and environmentally friendly [7]. Furthermore, according to previous research, Fenton-like reactions were also used to remove  $\text{Hg}^0$  from flue gas [21]. According to the reported results of Lu et al., the reduction of  $\text{Fe}^{3+}$  by hydrogen peroxide ( $\text{H}_2\text{O}_2$ ) efficiently induces  $\text{Hg}^0$  oxidation [22]. The reaction mechanism can be given by the following Eqs. (1)–(4) [9,23], where  $\cdot\text{OH}$ , which is highly conductive, is the key molecule necessary for the oxidation of  $\text{Hg}^0$ . In contrast, the direct reactions between  $\text{Hg}^0$  and  $\text{H}_2\text{O}_2$  are not the key reactions during the removal of  $\text{Hg}^0$  from flue gas [21]. After  $\text{Hg}^0$  is oxidized to  $\text{Hg}^{2+}$ , it can be quickly absorbed by the oxidation solution.

Wet Flue Gas Desulfurization (WFGD), is the most commonly used in coal-fired power plants worldwide for high sulfur dioxide ( $\text{SO}_2$ ) control [24]. As this kind of process uses limestone or lime slurry [25], calcium sulfite ( $\text{CaSO}_3$ ) is generated as an inevitable byproduct. Some research results have shown that  $\text{CaSO}_3$  solids with high BET surface areas are favorable for Hg retention [6]. However,  $\text{CaSO}_3$  can react with  $\text{Hg}^{2+}$  to form  $\text{HgSO}_3$ , which is unstable and results in the re-emission of  $\text{Hg}^0$  [1,6]. However, when the amount of  $\text{CaSO}_3$  is large enough,  $\text{Hg}(\text{SO}_3)_2^{2-}$  will be formed, which is much more stable and  $\text{Hg}^0$  can then be captured [1,6]. Liu et al. studied the simultaneous removal of  $\text{Hg}^0$ , NO and  $\text{SO}_2$  from flue gas using Fenton-like reagents ( $\text{H}_2\text{O}_2/\text{Fe}^{3+}$ ). These investigators also performed preliminarily studies of the effects of

several parameters, such as  $\text{H}_2\text{O}_2$  concentration,  $\text{Fe}^{3+}$  concentration, reaction temperature, solution pH, NO concentration and  $\text{SO}_2$  concentration [26]. However, in WFGD, the effect of  $\text{CaSO}_3$  on  $\text{Hg}^0$  removal and the role that NO, and  $\text{SO}_2$  play while using Fenton-like reagents ( $\text{H}_2\text{O}_2/\text{Fe}^{3+}$ ) has not been studied and clarified yet. Therefore, the role that  $\text{CaSO}_3$  and other parameters play during the purification of  $\text{Hg}^0$  requires further exploration.

This was the first study to investigate and discuss  $\text{Hg}^0$  removal efficiency in WFGD systems using a  $\text{H}_2\text{O}_2/\text{Fe}^{3+}$  solution with and without  $\text{CaSO}_3$ . The influence of operational conditions (temperature and pH), anions ( $\text{Cl}^-$  and  $\text{NO}_3^-$ ), and combustion flue gas components ( $\text{SO}_2$  and NO) on  $\text{Hg}^0$  removal efficiency in WFGD systems was also studied in the case of no  $\text{CaSO}_3$ , a 0.015%  $\text{CaSO}_3$  solution, and a 0.075%  $\text{CaSO}_3$  solution.

## 2. Experimental apparatus and methods

### 2.1. Chemical reagents

Reagents used in this research were all analytical reagents. Reagents including  $\text{H}_2\text{O}_2$  (30%, AR),  $\text{CaSO}_3$  (98%, AR), hydrogen chloride (HCl) (36.0%–38.0%, AR), sodium hydroxide (NaOH) (99.5%, AR), sodium chloride (NaCl) (99.5%, AR), sodium nitrate ( $\text{NaNO}_3$ ) (99.5%, AR), potassium chloride (KCl) (> 99.5%, AR), potassium permanganate ( $\text{KMnO}_4$ ) (> 99.5%, AR) and sulfuric acid ( $\text{H}_2\text{SO}_4$ ) (95–98%, AR) were all purchased from Beijing Chemical Co.. Ferric chloride ( $\text{FeCl}_3 \cdot 6\text{H}_2\text{O}$ ) (99.0%, AR) was purchased from Jinke Fine Chemical Research Institute of Tianjin.

### 2.2. Experimental apparatus

As shown in Fig. 1, the experimental facility can be divided into six parts: simulated flue gas generation system, mercury generator, gas distribution system, reaction system, gas analyzer and tail gas treatment.  $\text{N}_2$ ,  $\text{SO}_2$  and NO were provided from cylinders (1–3) (PQ-07QPP, China). An elemental mercury permeation tube (5) ( $40 \mu\text{g}/\text{m}^3$ , VICI Metronics Co., USA) was heated in a thermostatic water bath (4) (HH-ZK2, Yuhua Instrumental Company, Gongyi, China) to generate  $\text{Hg}^0$  vapor with 0.4 L/min of  $\text{N}_2$  as the carrier gas.  $\text{N}_2$ ,  $\text{SO}_2$  and NO were mixed with  $\text{Hg}^0$  in a Gas distribution system (6) (PQ-07QPP, China). The reaction occurred in a 0.6 L three necked flasks (8) (VICI Metronics Co., USA) surrounded by water at 60 °C in a thermostatic water bath (4) (HH-ZK2, Yuhua Instrumental Company, Gongyi). The outlet gas were dried through silica gel (9) (HH-ZK2, Yuhua Instrumental Company, Gongyi, China) before entering the mercury analyzer (10) (VM-3000, Germany) and the flue gas analyzer (12) (MRU-NOVA plus RCU, Germany), for the purpose of protecting the equipment and obtaining more accuracy for  $\text{Hg}^0/\text{SO}_2/\text{NO}$  detection.

### 2.3. Experimental procedure

$\text{N}_2$ ,  $\text{SO}_2$  and NO were metered through mass flow controllers (15–18) and mixed with  $\text{Hg}^0$  in a gas distribution system (6) at a total flow rate of 0.7 L/min. The simulated flue gas was with concentration ranges of 99.85%–100% for  $\text{N}_2$ , 200–1200 ppm for  $\text{SO}_2$  (if there was), and 50–300 ppm for NO (if there was). Before initiating the experiment, 50 mL slurry solution containing  $\text{CaSO}_3$  was freshly prepared and fed into the reactor with a continued stirring. The reaction started when the absorption solution of  $\text{H}_2\text{O}_2/\text{Fe}^{3+}$  was injected into the flask (8). The gas was bubbled through the aqueous solution with a gas distributor, a porous glass frit attached at the end of the gas supply line in flask (8). The generated gas bubble was about 2 mm and the average residence time of gas bubbles in the absorption solution was 2 s. NaCl and  $\text{NaNO}_3$  were used to provide  $\text{Cl}^-$  and  $\text{NO}_3^-$  to study the corresponding influence, respectively. The pH value of the solution was adjusted by HCl and NaOH, and it was obtained by a pH meter (7). The computer (11)
