This is a PDF file of an unedited manuscript that has been accepted for publication. As a service to our customers we are providing this early version of the manuscript. The manuscript will undergo copyediting, typesetting, and review of the resulting proof before it is published in its final form. Please note that during the production process errors may be discovered which could affect the content, and all legal disclaimers that apply to the journal pertain.

17 **ABSTRACT**

18 The present work aims to propose an empirical kinetic model based on sorption and the  
19 precursor state, which is capable of describing the variation in electrical resistances of  
20 olfactory sensors used in assembling a device known as the e-nose. In addition, a new  
21 approach to model its noise has been proposed by means of a stochastic differential equation.  
22 As regards its application, waste cooking oil from different sources was better characterized  
23 by this new model when compared to traditional techniques of data analysis for such device.
