Urea-SCR  
Ammonia storage  
Embeddable model  
Model-based control

## ABSTRACT

This paper investigates the characteristics of ammonia storage in actual SCR catalyst, which indicates that space velocities (SV), the exhaust temperature and  $\text{NH}_3:\text{NO}_x$  ratio (NSR) have different impacts on the saturated ammonia storage and saturated time. Thus, this paper proposes an embeddable SCR model consisting of a nonlinear ammonia storage model (NAS model) and a multiple variable resistance–capacitance model with time-delay (MVRC model), in order to quantify the ammonia storage and system-out  $\text{NO}_x$  concentration. After that, a model-based ammonia storage control strategy was developed to strike a better balance between high  $\text{NO}_x$  reduction efficiency and low ammonia slip.

## Introduction

With increasing demands for low engine emissions, the reduction of nitric oxides ( $\text{NO}_x$ ) produced by heavy duty diesel vehicles has become one of the main tasks. Urea-SCR systems performs very well in  $\text{NO}_x$  reduction, and thus can be served as a technology platform for further improvement. Therefore, urea-SCR system is recognized as the most preferred approach to meeting strict emission standards [1–6].

The urea-SCR is an effective way for  $\text{NO}_x$  reduction when the engine operates in the steady state condition. However, rapid change of engine loads leads to a rapid change of exhaust temperature, SV and urea dosage, which makes it difficult to obtain expected  $\text{NO}_x$  reduction and small  $\text{NH}_3$  slip simultaneously. Consequently, SCR control remains a great challenge in practice [7–11]. A better way to improve the performance of SCR system is on-board model-based SCR control, which allows a more accurate control of urea dosage. Weibel et al. proposed a  $\text{NH}_3$  load control strategy based on the normalized  $\text{NH}_3$  load model, which achieved a considerable  $\text{NO}_x$  reduction and an acceptable small  $\text{NH}_3$  slip

[12]. Junmin et al. proposed an ammonia storage distribution control method based on continuous stirred tank reactor model (CSTR model), which could effectively reduce SCR-outlet  $\text{NO}_x$  and  $\text{NH}_3$  emissions [13]. Yang et al. proposed a method combining neural network model with Fuzzy PID to meet both  $\text{NO}_x$  emission requirements and  $\text{NH}_3$  slip targets [14]. However, comparing with modeling researches on the discoveries of fundamental SCR reactions, the studies of embeddable models and experimental reports based on actual urea-SCR systems are relatively scarce [15].

This paper investigates the characteristics of ammonia storage in the actual SCR catalyst under different operating conditions of the engine. Then, in this paper, an embeddable SCR model is proposed to describe ammonia storage and transient response of  $\text{NO}_x$  concentration with the change of engine conditions and urea dosage. After that, a model-based control strategy of urea-SCR system is proposed.

## Materials and methods

### Experimental setup

The experimental setup consists of a 4.75 L diesel engine (Table 1), a 12 L  $\text{V}_2\text{O}_5\text{-WO}_3/\text{TiO}_2$  catalyst, the urea dosing system and a Wuhan Tianlan designed controller. The aftertreatment system is equipped with  $\text{NO}_x$  sensors and exhaust temperature sensors at both inlet and outlet of the catalyst converter, and an AVL AMA i60 emission analyzer and a Siemens ammonia analyzer

**Abbreviations:** NSR,  $\text{NH}_3:\text{NO}_x$  ratio; NAS model, nonlinear ammonia storage model; MVRC model, multiple variable resistance–capacitance model with time-delay; St, stability coefficient; SV, space velocities.

**Table 1**  
Engine information.

Engine model	Parameters
Features	Inline 4-cylinder, CRDI, TCI
Displacement	4.75 L
Cylinder bore × travel	110 mm × 125 mm
Compression ratio	17.5
Rated power	120 kw at 2500 rev/min
Maximum torque	660 Nm at 1200–1600 rev/min

are located at the tailpipe. The schematic of the experimental setup is shown in Fig. 1.

#### Research on the characteristics of ammonia storage

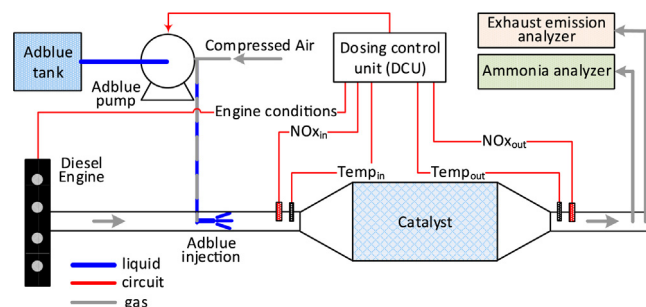

The ammonia storage is defined as the amount of ammonia stored in the catalyst, which can be calculated through the urea dosage, the mass flux and NO<sub>x</sub> concentration of engine exhaust, and both the NO<sub>x</sub> and NH<sub>3</sub> concentration after the SCR catalyst. The urea dosage is determined by the engine-out NO<sub>x</sub> concentration, the NH<sub>3</sub>:NO<sub>x</sub> ratio, the maximal NO<sub>x</sub> conversion efficiency (the NH<sub>3</sub> slip is kept at 10 ppm), the exhaust temperature and mass flux.

The urea dosage and ammonia storage are calculated by Eqs. (1) and (2):

$$V_{\text{urea}} = \frac{MG_{\text{urea}} \times v \times M_{\text{exh}} \times NO_{x,\text{In}} \times C_{\text{max}} \times \text{NSR}}{MG_{\text{exh}} \times \rho_{\text{urea}} \times MF_{\text{urea}} \times 10^5} \quad (1)$$

$$\text{Strg}_{\text{NH}_3} = \int \frac{MG_{\text{NH}_3} \times [(MF_{\text{urea}} \times V_{\text{urea}} \times \rho_{\text{urea}} / MG_{\text{urea}} \times v) - ((\text{DeNO}_x + \text{NH}_{3,\text{slip}}) \times M_{\text{exh}} / MG_{\text{exh}} \times 10^3)]}{3600} \quad (2)$$

where  $V_{\text{urea}}$  is the urea dosage (ml/h);  $\rho_{\text{urea}}$  is the urea density (g/ml);  $M_{\text{exh}}$  is the exhaust mass flux (kg/h);  $NO_{x,\text{In}}$  is the engine-out NO<sub>x</sub> concentration (ppm);  $C_{\text{max}}$  is the maximal NO<sub>x</sub> conversion efficiency (%);  $\text{DeNO}_x$  is the amount of NO<sub>x</sub> reduction (ppm);  $\text{NH}_{3,\text{slip}}$  is the outlet NH<sub>3</sub> concentration (ppm);  $\text{Strg}_{\text{NH}_3}$  is the current ammonia storage (g); NSR is the NH<sub>3</sub>:NO<sub>x</sub> ratio;  $MF_{\text{urea}}$  is the urea mass fraction in AdBlue ( $MF_{\text{urea}} = 0.325$ );  $MG_{\text{urea}}$ ,  $MG_{\text{NH}_3}$  and  $MG_{\text{exh}}$  are the molar mass of urea, NH<sub>3</sub> and exhaust gas (g/mol) respectively and  $v$  is the stoichiometric coefficients of urea decomposition ( $v = 0.5$ ).

**Fig. 1.** Engine and urea-SCR aftertreatment system.

A series of experiments were conducted at fixed engine operating conditions with different speed and temperature. Meanwhile, the interval for speed was 100 rpm and the interval for temperature was 25 °C. Then, the results under different temperatures and SV were obtained, as shown in Fig. 2.

In the experiment, the engine was running at a steady operating condition. The engine-out NO<sub>x</sub> levels varied with different engine conditions and the urea was injected into the exhaust pipe with a fixed NSR. According to the required NO<sub>x</sub> conversion efficiency, the NSR was set to 0.9. The injection ended when the NO<sub>x</sub> concentration after catalyst achieved stability. Meanwhile, in this paper, the ammonia storage at this time is defined as the saturated ammonia storage whereas the time that the saturated ammonia storage is realized is defined as saturated time.

A criterion for the stability of outlet NO<sub>x</sub> concentration is calculated by Eq. (3):

$$St = \frac{\int_{t-10}^t NO_{x,\text{Out}} - \int_{t-20}^{t-10} NO_{x,\text{Out}}}{\int_{t-20}^{t-10} NO_{x,\text{Out}}} \quad (3)$$

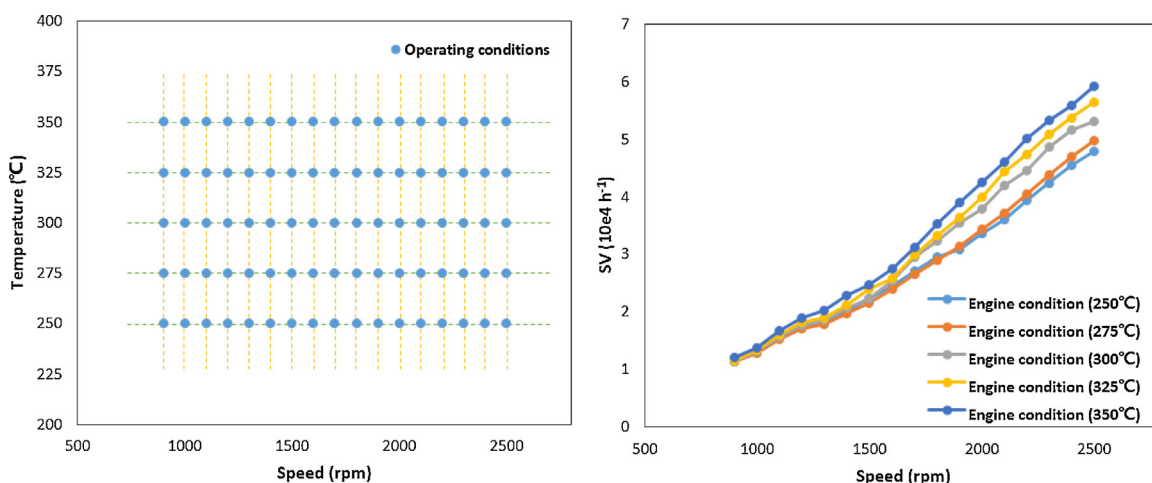

where  $St$  refers to the stability coefficient;  $t$  is time (s) and  $NO_{x,\text{Out}}$  is the NO<sub>x</sub> concentration after catalyst (ppm).

In this paper, the outlet NO<sub>x</sub> concentration is considered as stable when the  $St$  is below 1%.

#### The characteristics of ammonia storage

##### Effect of exhaust temperature on ammonia storage process

The effect of exhaust temperature on the ammonia storage process was investigated when the SV was maintained at  $1 \times 10^4$ ,
