Photocatalysis

**Abstract** Spinel structure nickel ferrite (NiFe<sub>2</sub>O<sub>4</sub>) doped graphitic carbon nitride (g-C<sub>3</sub>N<sub>4</sub>) photocatalyst NiFe<sub>2</sub>O<sub>4</sub>/g-C<sub>3</sub>N<sub>4</sub> was synthesized by the coprecipitation route to enhance the photocatalytic activity for the visible-light driven degradation of methyl orange. The NiFe<sub>2</sub>O<sub>4</sub> doping content is responsible for the microstructure and photocatalytic activity of NiFe<sub>2</sub>O<sub>4</sub>/g-C<sub>3</sub>N<sub>4</sub> samples. Compared with pure NiFe<sub>2</sub>O<sub>4</sub> and g-C<sub>3</sub>N<sub>4</sub>, the 2-NiFe<sub>2</sub>O<sub>4</sub>/g-C<sub>3</sub>N<sub>4</sub> composite with NiFe<sub>2</sub>O<sub>4</sub> doping of 2.0 wt% exhibited excellent photocatalytic activity and superior stability after five runs for degrading methyl orange under visible light irradiation. The catalytic activity of 2-NiFe<sub>2</sub>O<sub>4</sub>/g-C<sub>3</sub>N<sub>4</sub> sample produced using the coprecipitation route was higher than those of conventional 2-NiFe<sub>2</sub>O<sub>4</sub>/g-C<sub>3</sub>N<sub>4</sub> bulks prepared by the impregnation approach. The prepared samples for the photocatalytic degradation of methyl orange followed pseudo-first-order reaction kinetics. It's ascribed to the synergistic effect between NiFe<sub>2</sub>O<sub>4</sub> and g-C<sub>3</sub>N<sub>4</sub>, which can inhibit the recombination of photoexcited electron-hole pairs, accelerate photoproduced charges separation, and enhance the visible light absorption.

has been widely paid attention to address the environmental remediation and solar energy conversion [1–3]. The semiconductor catalysts, such as TiO<sub>2</sub>, Fe<sub>2</sub>O<sub>3</sub>, ZnO, and CdS, are intensively performed for the production hydrogen from splitting water, degradation of organic pollutants, synthesis of hydrocarbon compounds, and methanation of carbon oxide [4–11]. However, these catalysts are not suitable for the effective utilization of solar energy under visible light irradiation due to large band gap energy, fast recombination of electron-hole pairs, and low surface area [12–14]. It is thus urgent to develop novel semiconductor catalysts with effective photocatalysis in visible-light applications.

Please cite this article in press as: Y. Liu et al., NiFe<sub>2</sub>O<sub>4</sub>/g-C<sub>3</sub>N<sub>4</sub> heterojunction composite with enhanced visible-light photocatalytic activity, Journal of Saudi Chemical Society (2017), <http://dx.doi.org/10.1016/j.jscs.2017.08.002>

Graphitic carbon nitride (g-C<sub>3</sub>N<sub>4</sub>), a metal-free polymeric semiconductor with the band gap of 2.7–2.8 eV, is one of the most potential visible-light catalysts due to its high condensation and tri-s-triazine ring structure [15–17]. Nevertheless, g-C<sub>3</sub>N<sub>4</sub> is greatly deactivated by low electrical conductivity, high recombination of charge carriers, and deficient absorption of solar energy above 460 nm [18–22]. Several strategies such as doping modification, electronic structure modulation, and constructing g-C<sub>3</sub>N<sub>4</sub>-based composites are attempted to broaden visible-light absorption and strengthen photocatalytic activity of g-C<sub>3</sub>N<sub>4</sub> materials [23–26]. The doping of inorganic particles into g-C<sub>3</sub>N<sub>4</sub> matrix is an effective approach to modify the energy band configuration and electronic structure [27–30]. The effective anchoring of inorganic or organic materials on the g-C<sub>3</sub>N<sub>4</sub> surface favors the optimized visible-light photoactivity. Combination between g-C<sub>3</sub>N<sub>4</sub> and semiconductor such as Ag<sub>3</sub>VO<sub>4</sub>, CdS, ZnO, Ag<sub>2</sub>WO<sub>4</sub>, NiS, and WO<sub>3</sub> can enhance photocatalytic activity under visible-light irradiation because of the cooperative effect of heterojunction structure with interfacial charge-transfer effects and effective light harvesting [31–36]. In recent years, spinel structure ferrite (MFe<sub>2</sub>O<sub>4</sub>, M = Zn, Ni, and Co) based samples have aroused great interest for water splitting into hydrogen and degradation of organic pollutants [37–45]. Compared with pure NiFe<sub>2</sub>O<sub>4</sub> with inferior photocatalytic activity even though in the Fenton reaction, the matching energy level of g-C<sub>3</sub>N<sub>4</sub> and NiFe<sub>2</sub>O<sub>4</sub> is contributed to the separation and immigration of electron-hole pairs [37,38]. The g-C<sub>3</sub>N<sub>4</sub>-based heterojunction photocatalysts doped with MFe<sub>2</sub>O<sub>4</sub> can also accelerate the electron-hole separation, inducing to the fascinating optical property. However, the detailed fundamental study of spinel structure NiFe<sub>2</sub>O<sub>4</sub> doped g-C<sub>3</sub>N<sub>4</sub> (NiFe<sub>2</sub>O<sub>4</sub>/g-C<sub>3</sub>N<sub>4</sub>) for the visible-light driven degradation of methyl orange is scarce in previous works.

This work focused on the fabrication of g-C<sub>3</sub>N<sub>4</sub>-based heterojunction material combined with spinel NiFe<sub>2</sub>O<sub>4</sub> (NiFe<sub>2</sub>O<sub>4</sub>/g-C<sub>3</sub>N<sub>4</sub>) via a coprecipitation route (NiFe/CN), and performed for the photocatalytic degradation of methyl orange under visible light irradiation. Compared with pure NiFe<sub>2</sub>O<sub>4</sub> and g-C<sub>3</sub>N<sub>4</sub>, NiFe<sub>2</sub>O<sub>4</sub>/g-C<sub>3</sub>N<sub>4</sub> sample with optimized NiFe<sub>2</sub>O<sub>4</sub> doping (2-NiFe/CN) presented excellent visible-light photocatalytic activity and slight deterioration for the degradation of methyl orange. The 2-NiFe/CN bulks exhibited higher photodegradation efficiency than that of 2-NiFe/CN-*D* generated by impregnation method.

## 2. Experimental

### 2.1. Preparation of catalysts

NiFe<sub>2</sub>O<sub>4</sub>/g-C<sub>3</sub>N<sub>4</sub> composites (NiFe/CN) with NiFe<sub>2</sub>O<sub>4</sub> doping content of 1–5 wt% were synthesized using a coprecipitation approach. All chemicals were used without further purification. In a typical process, melamine (C<sub>3</sub>H<sub>6</sub>N<sub>6</sub>) and ammonia (NH<sub>3</sub>·H<sub>2</sub>O) were added into 200 mL dimethyl sulfoxide (C<sub>2</sub>H<sub>6</sub>OS) to form solution A. Cyanuric acid (C<sub>3</sub>H<sub>3</sub>N<sub>3</sub>O<sub>3</sub>), nickel nitrate (Ni(NO<sub>3</sub>)<sub>2</sub>·6H<sub>2</sub>O), and ferric nitrate (Fe(NO<sub>3</sub>)<sub>3</sub>·6H<sub>2</sub>O) in stoichiometric proportion were dissolved into 200 mL dimethyl sulfoxide (C<sub>2</sub>H<sub>6</sub>OS) solution to form solution B. The solution B was slowly added to solution A under vigorous stirring at room temperature. The above mixture solution was then centrifuged, washed with ethanol and distilled water

four times, dried at 353 K for 12 h, and calcined at 823 K for 3 h to obtain NiFe/CN sample. According to above route, NiFe/CN samples doped with NiFe<sub>2</sub>O<sub>4</sub> content of 1–5 wt% were generated and labeled as 1-NiFe/CN, 2-NiFe/CN, 3-NiFe/CN, 4-NiFe/CN, and 5-NiFe/CN. The g-C<sub>3</sub>N<sub>4</sub> produced via the coprecipitation approach and the thermal polymerization route was denoted as g-C<sub>3</sub>N<sub>4</sub> and g-C<sub>3</sub>N<sub>4</sub>-*D*, respectively. g-C<sub>3</sub>N<sub>4</sub>-*D* bulks were prepared by a traditional thermal polymerization route, of which 10 g of urea was placed in an alumina crucible and annealed at 823 K for 3 h to collect yellow product [46–48]. NiFe<sub>2</sub>O<sub>4</sub>/g-C<sub>3</sub>N<sub>4</sub>-*D* (NiFe/CN-*D*) sample was generated by the impregnation route. Typically, 1 g of g-C<sub>3</sub>N<sub>4</sub>-*D* bulks was added to 100 mL aqueous solutions including different amounts of Ni(NO<sub>3</sub>)<sub>2</sub>·6H<sub>2</sub>O and Fe(NO<sub>3</sub>)<sub>3</sub>·6H<sub>2</sub>O in stoichiometric proportion. The above solution was continually stirred at room temperature for 4 h, stirred at 353 K to evaporate excessive water, dried at 373 K for 12 h, and calcined at 823 K for 3 h.

### 2.2. Characterization of catalysts

XRD patterns of the fabricated samples were taken on a Bruker D8 Advance X-ray Powder Diffractometer equipped with a Cu K $\alpha$  radiation ( $\lambda = 0.15406$  nm). Fourier transforms infrared spectra (FT-IR) were obtained on Bruker VEC-TORTM 22 FTIR spectrometer with the region of 400–4000 cm<sup>−1</sup>. X-ray photoelectron spectroscopy (XPS) patterns were collected by a Kratos Axis UltraDLD equipped with a hemispherical electron energy analyzer. The NiFe<sub>2</sub>O<sub>4</sub> doping mass was analyzed by inductively coupled plasma optical emission spectrometry (ICP-OES) method on Varian 710-ES equipped with a 1.12 megapixel CCD detector. N<sub>2</sub> sorption isotherms were achieved using a Quantachrome autosorb automated gas sorption analyzer (NOVA 2200e). Scanning electron microscopy (SEM) images were recorded with a JSM-5610LV/INCA microscope. Transmission electron microscopy (TEM) images were obtained by a Philips Tecnai G220 operated at 200 kV. The high resolution transmission electron microscopy (HRTEM) images were detected on JEM-2100 operated at 200 kV. UV–visible diffuse reflectance spectra (UV–vis DRS) was recorded on Shimadzu UV-2101 PC spectrophotometer with an ISR-240A integrating sphere attachment. The photoluminescence (PL) spectra were observed on Varian Cary Eclipse spectrometer. The electron spin resonance (ESR) signals of radicals were obtained on a Bruker model ESR JES-FA200 spectrometer.

### 2.3. Evaluation of catalysts

The NiFe<sub>2</sub>O<sub>4</sub>/g-C<sub>3</sub>N<sub>4</sub> samples were performed for the photodegradation of methyl orange under visible light region generated from a 300 W Xe lamp with a 420 nm cutoff filter. In a typical process, 0.2 g sample was added to the methyl orange solution (200 mL, 10 mg L<sup>−1</sup>) and magnetically stirred in dark for 2 h to achieve absorption–desorption equilibrium before reaction. At regular time intervals, 10 mL above solution was sampled and centrifuged to remove the solid particles. The concentration of methyl orange was evaluated by a Hitachi U-3010 UV–vis spectrophotometer. The photocatalytic stability of NiFe<sub>2</sub>O<sub>4</sub>/g-C<sub>3</sub>N<sub>4</sub> samples was performed for five cycles. The first cycle of experiment was carried out for 60 min under
