performance; Reversibility

**ABSTRACT**

Two infrared reflective coatings recently developed as part of the EFFESUS European  
research project are characterized and evaluated in this paper. Thermal performance,  
durability, compatibility with historic fabric, and reversibility are all analysed. The results of  
extensive research that include laboratory analysis of selected substrates, measurements on a  
large-scale traditional masonry mock-up, thermodynamic simulations, and finally application  
in to a real historic building in Istanbul, all support the potential of the new coatings to  
improve the thermal performance of historic buildings, in keeping with their visual integrity  
and cultural value. Besides their reflective properties, proven by the thermal stress reductions  
on the treated surfaces, the new coatings are characterized by low visual impact, easy  
application, material compatibility, and reversibility after application, as well as durability  
over time.

**1. INTRODUCTION**

Reflective coatings are passive solutions that reflect a proportion of incidental infrared (IR)  
surface radiation. They contribute to mitigation of the effects of the heat island phenomenon  
at an urban level, while decreasing the cooling demand in summer and improving indoor  
thermal comfort within the building. The literature contains immense scientific effort to  
design geo-engineering solutions for the effective mitigation of climate change and the  
consequent heat island effect, using high albedo materials for “cool roofs”, urban paving and  
building envelopes [1]. The development and the environmental and energetic performance of  
cool coatings technologies are widely discussed in two review articles [2; 1]. The first  
generation of cool coatings consisted of natural materials (generally, natural stone aggregates)  
with a high albedo (higher than 0.8), light colours and walkable surfaces for application  
principally on roofs and pavements [1; 3; 4]. Then, a second generation of non-white  
materials with an albedo higher than the first generation of coatings was also recently
