9 **Abstract:** The variety of occupant behaviors in buildings have led to a significant mismatch  
10 between simulated building energy performance and measured one. It is crucial to collect real  
11 occupant behaviors in buildings to achieve accurate simulation purpose, although there exists a  
12 great challenge due to the cost of monitoring devices and privacy concerns. This study proposed an  
13 inexpensive and minimally intrusive method, to recognize behavior information from environment  
14 parameters by data mining approach. To validate this method, experiments were conducted in three  
15 bedrooms. Two types of classification algorithms were developed to recognize AC operations from  
16 the experiment data of indoor air temperature and relative humidity. Two types of recognition rules  
17 were generated from algorithm training in one dataset, and tested in the other datasets. Based on the  
18 testing results, the performance of the two algorithms were evaluated and compared. The results  
19 indicated that the C4.5 decision tree algorithm was not suitable for mining AC operations, while the  
20 curve description algorithm had good performance in processing the time-series curves of air  
21 temperature and relative humidity. Through this experiment, it is confirmed that AC operations can  
22 be recognized from indoor air temperature and relative humidity by data mining approach. The
