This is a PDF file of an unedited manuscript that has been accepted for publication. As a service to our customers we are providing this early version of the manuscript. The manuscript will undergo copyediting, typesetting, and review of the resulting proof before it is published in its final form. Please note that during the production process errors may be discovered which could affect the content, and all legal disclaimers that apply to the journal pertain.

9 **Abstract**

10 Perforation of circular 2024-T3(51) aluminum alloy plates of various normalized
11 thicknesses by a rigid spherical projectile is considered as a benchmark problem to validate material
12 plasticity and fracture models. A new set of experiments with circular 2024-T3(51) aluminum alloy
13 plates and AISI 52100 alloy steel spheres was conducted in order to augment available in literature
14 experimental data and to form more precise reference solution for the benchmark problem.
15 Numerical simulations of a plate perforation using Johnson-Cook plasticity model with two sets of
16 parameters, Johnson-Cook fracture criterion with one set of fitting parameters and pressure and
17 Lode dependent ductile fracture criterion with three sets of material constants are performed.
18 Problem formulation, types of plasticity and fracture models and their parameters are estimated
19 independently in the context of their effect on the accuracy of numerical solution. Ballistic limit
20 velocity and residual velocity tests are employed for validation procedure. With one of the
21 considered formulation-models combination quantitative discrepancy of less than 10% and good
22 and physically sound qualitative agreement with the experiment were obtained.

23
24 **Keywords**

25 Plasticity model, fracture criterion, plate perforation, numerical simulation, experiment.
