## 10 11 **ABSTRACT**

12 Automatic identification and localization of rebar from ground penetrating radar (GPR)  
13 data has been a research topic of great interest. This paper presents an automated rebar  
14 picking algorithm for GPR data of concrete bridge decks. The algorithm is based on the  
15 Limited and Simplified Hyperbolic Summation (LSHS) technique in which the width of  
16 migration is limited and a counter is used to check if a hyperbolic signature exist in a sub-  
17 region of GPR image. More specifically, after a time-zero correction, each pixel in the raw  
18 GPR image with a positive amplitude will be migrated, as it is usually done with the  
19 conventional hyperbolic summation (HS) technique. However, for each pixel to be migrated,  
20 the width of migration is limited in the horizontal direction and a unit value will be used for  
21 migration, instead of the true amplitude values of the pixels. In the obtained image, the pixels  
22 containing rebar peaks will normally have the intensity values close to the number of pixels  
23 corresponding to the width of migration and, therefore, can be picked. Whereas the method is  
24 rather straightforward and simple to develop, its implementation on GPR data of two concrete  
25 bridge decks has shown good results. First, the GPR condition maps obtained from the
