9 Abstract

10 In this paper, with the goal of maximizing the power production of a wind farm and reducing the wake effect
11 resulting from front-end turbines, we present a new optimization method based on the generation of pseudo-
12 random numbers as a mathematical approach; we have used this method along with the Jensen linear wake
13 model in order to study optimal wind turbine positioning in a farm of given dimensions. For this purpose, a
14 computer program has been developed to carry out numerical simulations based on the maximum total power
15 produced. Using a typical wind turbine for uniform and unidirectional wind speed, the simulation results that
16 we have obtained are presented and discussed. Compared to previous works based on genetic algorithms and
17 viral basis methods, this optimization has yielded recorded enhancements of up to 6.5% on resulting wind
18 farm power. Furthermore, we have found that an optimum number of wind turbines can be properly
19 determined for any given wind farm.

20 **Keywords:** Wind farm; Wind turbine wake; Random number generation; Optimization; Numerical
21 simulation.
