7 Abstract

8 The past quarter century has witnessed development of advanced modeling
9 approaches, such as stochastic and agent-based modeling, to sustainably manage
10 water systems in the presence of deep uncertainty and complexity. However, all
11 too often data inputs for these powerful models are sparse and outdated, yield-
12 ing unreliable results. Advancements in sensor and communication technologies
13 have allowed for the ubiquitous deployment of sensors in water resources systems
14 and beyond, providing high-frequency data. Processing the large amount of het-
15 erogeneous data collected is non-trivial and exceeds the capacity of traditional
16 data warehousing and processing approaches. In the past decade, significant
17 advances have been made in the storage, distribution, querying, and analysis of
18 big data. Many tools have been developed by computer and data scientists to
19 facilitate the manipulation of large datasets and create pipelines to transmit the
20 data from data warehouses to computational analytic tools. A generic frame-
21 work is presented to complete the data cycle for a water system. The data cycle
22 presents an approach for integrating high-frequency data into existing water-
23 related models and analyses, while highlighting some of the more helpful data
24 management tools. The data tools are helpful to make sustainable decisions,
25 which satisfy the objectives of a society. Data analytics distribution tool Spark
26 is introduced through the illustrative application of coupling high-frequency de-
27 mand metering data with a water distribution model. By updating the model
28 in near real-time, the analysis is more accurate and can expose serious misin-
29 terpretations.

31 water systems, modeling, big data, automation, Hadoop, Apache Spark, cloud
32 computing
33

34 1. Introduction

35 The water resources community relies on computer models to conceptualize
36 and reproduce behavior of systems, aiding in planning, design, and analysis.
