Abstract

Significant advances in wireless communication technologies have led to the emergence and proliferation of a wide range of mobile devices and mobile services. However, the use of various cloud servers has made the traditional single-server architecture, where we have one server and many users, inefficient in terms of its performance. To address this drawback, multi-server architectures have been proposed. Password or smart card-based authentication schemes suffer from poor security in the multi-server environment and as a result biometrics have become a preferred choice for secure and robust authentication because of its close link with the physical characteristics of an individual. Recently Kumari and Li et al. proposed a biometrics-based authentication scheme for multi-server environment. However, we found that their scheme fails to meet user anonymity requirement and is vulnerable to several attacks. First, we describe
