Point set denoising

Normal voting tensor

Binary eigenvalues optimization

Quadratic error metric

## ABSTRACT

In many applications, point set surfaces are acquired by 3D scanners. During this acquisition process, noise and outliers are inevitable. For a high fidelity surface reconstruction from a noisy point set, a feature preserving point set denoising operation has to be performed to remove noise and outliers from the input point set. To suppress these undesired components while preserving features, we introduce an anisotropic point set denoising algorithm in the normal voting tensor framework. The proposed method consists of three different stages that are iteratively applied to the input: in the first stage, noisy vertex normals, are initially computed using principal component analysis, are processed using a vertex-based normal voting tensor and binary eigenvalues optimization. In the second stage, feature points are categorized into corners, edges, and surface patches using a weighted covariance matrix, which is computed based on the processed vertex normals. In the last stage, vertex positions are updated according to the processed vertex normals using restricted quadratic error metrics. For the vertex updates, we add different constraints to the quadratic error metric based on feature (edges and corners) and non-feature (planar) vertices. Finally, we show our method to be robust and comparable to state-of-the-art methods in several experiments.

## 1. Introduction

Point sets arise naturally in almost all kinds of three-dimensional acquisition processes, like 3D scanning. As early as 1985, they have been recognized as fundamental shape representations in computer graphics, [1]. Thus, they have manifold applications e.g. in face recognition [2], traffic accident analysis [3], or archeology [4].

However, during the acquisition process, due to mechanical limitations and surrounding conditions, noise and outliers are inevitably added to the point set. These artifacts have to be removed in a post-processing step to obtain a cleaned point set, which can be used in further steps like surface reconstruction, computer aided design (CAD), or 3D printing. There exists a variety of denoising methods focused on removing outliers and noise from the input point set to create a high fidelity output. These methods do not only aim at removing the undesired components, but also try to preserve sharp features of the geometry. High frequency components like corners or edges should be preserved and not be smoothed out. This is a challenging task as both features and noise

are high frequency components and thus ambiguous in their nature.

Most state-of-the-art denoising methods are designed to work on triangle meshes. Compared to this setup, working on point sets and preserving sharp features is more difficult as explicit connectivity information is not present. Also, we assume the input to be given without any normals. However, as point sets take up less storage space and as the surface reconstruction is easier on a noise-free point set, we aim for an intrinsic smoothing method to work directly on the noisy point set input.

Our method is focused on the preservation of sharp features while removing noise and outliers from an input point set. The proposed algorithm follows an iterative three-step point set denoising scheme. (1) Noisy vertex normals processing using a vertex-based *normal voting tensor* (NVT) and *binary eigenvalues optimization* (BEO) similar to [5]. (2) Feature points detection using an anisotropic covariance matrix. For the update of vertex positions, we use (3) a variation of the quadratic error norm adjusted to different kinds of feature points. Steps (1) to (3) are iteratively applied until a satisfactory output has been generated.

## 40 1.1. Related work

## 41 1.1.1. Point-based methods

42 In general, point sets appear as natural output of 3D scan de-  
 43 vices. The increase in computational costs while processing poly-  
 44 gonal meshes with growing size is partly responsible that points got  
 45 recognized as primitives for surface representation, cf. [6]. One ma-  
 46 jor drawback in this approach is the absence of connectivity in-  
 47 formation, which sets the task to declare surface normals. Here,  
 48 [6] especially proposes a definition utilizing surfels, which are  
 49 points equipped with normals. Usually point clouds do not carry  
 50 normals, so we have to rely on methods which determine these  
 51 robustly and with high quality. The authors Mitra and Nguyen  
 52 [7] suggest a calculation of point set normals and an analysis un-  
 53 der consideration of density, neighborhood sizes, and the presence  
 54 of noise.

55 We are interested in point set denoising coupled with fea-  
 56 ture preservation. There are several works approaching these two  
 57 properties directly. A first one was published by Fleishman et al.  
 58 [8] – serving as a representative despite the fact that it deals with  
 59 meshes instead of point clouds. As it does not use the mesh infor-  
 60 mation, so it can be transferred to the point set setting. They use  
 61 a bilateral filtering of points in normal direction in local neigh-  
 62 borhoods. Another one is the anisotropic smoothing of point sets [9],  
 63 where the authors use an anisotropic geometric curvature flow. Be-  
 64 sides the high dependency on suitable neighborhoods, which the  
 65 authors cannot compute directly, the proposed algorithm does not  
 66 detect features explicitly, but incorporates feature detection into an  
 67 anisotropic Laplacian. The more recent work [10] is based on the  
 68 idea of sparsity methods and includes  $L_0$  minimization. Originating  
 69 from image denoising, they set up an energy consisting of the 3D  
 70 signal to be optimized coupled with an  $L_0$  optimization applied to  
 71 a differential operator on the signal.

72 Processing of normals, point positions, and an edge-aware up-  
 73 sampling offers the opportunity for an iterative application. In this  
 74 setting, we are going to compare our algorithm with that of [11],  
 75 called “moving robust principal component analysis” (MRPCA). The  
 76 idea is – like the previous – based on sparsity methods, which  
 77 takes sparsity-algorithms and adapt them to geometry processing  
 78 problems. They perceive the point cloud as a collection of over-  
 79 lapping two-dimensional subspaces and do not rely – in contrast  
 80 to other procedures – on oriented normals as input. The method  
 81 is robust against outliers and capable of denoising the point cloud  
 82 while handling sharp features.

83 Recently, Zheng et al. [12] proposed an extension of edge-aware  
 84 image processing and mesh denoising to point clouds. In their  
 85 four-staged approach, feature candidates are detected, employing a  
 86 feature structure by the  $l_1$ -medial skeleton, calculating and equip-  
 87 ping these with multiple normals, and selecting guiding normals  
 88 by using kNN patches with its normals being most consistent. In  
 89 this terms, the algorithm is even capable of high intensive noise  
 90 while preserving important geometric features.

## 91 1.1.2. Surface reconstruction with feature preservation

92 One of the processes most affected by noise and outliers in a  
 93 point set is that of surface reconstruction. A thorough introduction  
 94 is given in the survey [13]. All following techniques aim at preserv-  
 95 ing features while simultaneously perform denoising in the surface  
 96 reconstruction process. In the context of local smoothness priors,  
 97 the moving least squares (MLS) approach has a major impact. De-  
 98 veloped in large parts by Levin [14], MLS underwent a lot of modi-  
 99 fications. Guennebaud and Gross [15] modified the MLS idea by re-  
 100 placing the concept of finding well-defined tangent planes by fit-  
 101 ting spheres as higher order approximations to the surface. This  
 102 change makes the method more robust – especially in sparsely  
 103 sampled regions, where a well defined tangent plane might not

exist. Their method is denoted as “algebraic point set surfaces” 104  
 (APSS) and will serve as comparison to our algorithm. The method 105  
 of Öztireli et al. [16] aims at overcoming the sensitivity of MLS to 106  
 outliers and the effect of smoothing out small or sharp features. 107  
 They combine MLS with local kernel regression to create a new im- 108  
 plicit description of the surface, making it robust to noise, outliers, 109  
 and even sparse sampling. Their method of “robust implicit mov- 110  
 ing least squares” (RIMLS) will be the third algorithm we compare 111  
 to. More recently, Chen et al. [17] set their focus on a new MLS for- 112  
 malism using higher-order approximations – like APSS – incorpo- 113  
 rating discrete non-oriented gradient fields, yielding a continuous 114  
 implicit representation. 115

Turning to hierarchical partitioning, Ohtake et al. [18] propose 116  
 “multi-level partitioning of unity implicits” (MPU). Their technique 117  
 consists of an octree-based top-down structure, where points in a 118  
 cell and nearby are approximated by either a bivariate quadratic 119  
 polynomial or an algebraic trivariate quadric. An adjustment pa- 120  
 rameter for the level of smoothness guarantees the handling of 121  
 noise with respect to an error residual tolerance. 122

Considering piecewise smooth priors and partition based meth- 123  
 ods, Fleishman et al. [19] concentrate with their robust moving 124  
 least squares (RMLS) on the handling of sharp features. They use 125  
 the robust statistics tool of forward-search paradigm to choose 126  
 small sets of points excluding outliers, continuing through the 127  
 cloud, and evaluating observations monitored by statistical esti- 128  
 mates. Wang et al. [20] robustly compute a feature preserving nor- 129  
 mal field by mean-shift clustering and a least median of squares 130  
 (LMS) regression scheme, providing local partitions, to which edge- 131  
 preserving smoothing is applied by fitting multiple quadrics. Due 132  
 to the locality, feature fragmentation at sharp edges may occur. 133

Taking sparsity and neighboring normals into account, Avron 134  
 et al. [21] use global  $L_1$  optimization on these normals, observ- 135  
 ing that differences between them should be sparse, yet large val- 136  
 ues should reflect sharp features. Similar to the approach in RIMLS, 137  
 [22] suggests the edge-aware resampling (EAR) of the point cloud. 138  
 This is a feature-sensitive method under the guidance of the lo- 139  
 cally optimal projection (LOP) [23] in a two-staged approach, start- 140  
 ing their robust smoothing and resampling process in regions with 141  
 similar normal distribution, while approaching the edges in terms 142  
 of both smoothing and resampling in a second step. 143

## 144 1.2. Contribution

On a noisy point set, it is a challenging task to decouple noise 145  
 components and sharp features, which is essential for a noise-free 146  
 point set reconstruction. As shown in Fig. 1, our algorithm consists 147  
 of three different stages, which are iteratively applied until a satis- 148  
 factory output has been computed. In the first stage, which is ver- 149  
 tex normal filtering, we extend the concept of face normal process- 150  
 ing of Yadav et al. [5] to the more general setup of vertex normal 151  
 processing. Although our vertex normal processing is similar to the 152  
 face normal processing of Yadav et al. [5], we define a vertex-based 153  
 Normal Voting Tensor (NVT) based on the variation of vertex nor- 154  
 mals. In terms of noise sensitivity, vertex normals are more sensi- 155  
 tive compared to face normals. Therefore, we modify the weight- 156  
 ing scheme in the neighborhood selection to make the algorithm 157  
 robust against different levels of noise. Noise and sharp features 158  
 are decoupled using the spectral analysis of the vertex-based NVT 159  
 and noise components are suppressed using Binary Eigenvalues Op- 160  
 timization (BEO). In the second stage, we introduce an anisotropic 161  
 covariance matrix using the filtered vertex normals to detect fea- 162  
 ture points (edges and corners) robustly on the noisy input point 163  
 set. In the last stage, we update the vertex positions based on 164  
 quadratic error metrics. A corresponding quadratic error metric is 165  
 used based on different feature points. The proposed vertex update 166
