Collaborative charging

ABSTRACT

Wireless energy transfer is used to fundamentally address energy management problems in Wireless Rechargeable Sensor Networks (WRSNs). In such networks mobile entities traverse the network and wirelessly replenish the energy of sensor nodes. In recent research on collaborative wireless charging, the mobile entities are also allowed to charge each other.

In this work, we enhance the collaborative feature by forming a hierarchical charging structure. We distinguish the Chargers in two groups, the hierarchically lower Mobile Chargers which charge sensor nodes and the hierarchically higher Special Chargers which charge Mobile Chargers. We define the Coordination Decision Problem and prove that it is NP-complete. Also, we propose a new protocol for 1-D networks which we compare with a state of the art protocol. Motivated by the improvement in 1-D networks, we propose and implement four new collaborative charging protocols for 2-D networks, in order to achieve efficient charging and improve important network properties. Our protocols are either centralized or distributed, and assume different levels of network knowledge.

Extensive simulation findings demonstrate significant performance gains, with respect to non-collaborative state of the art charging methods. In particular, our protocols improve several network properties and metrics, such as the network lifetime, routing robustness, coverage and connectivity. A useful feature of our methods is that they can be suitably added on top of non-collaborative protocols to further enhance their performance.

1. Introduction and contribution

In Wireless Sensors Networks (WSNs) the sensor nodes are equipped with small batteries and thus, the lifetime of the network is limited. Although there are several approaches that try to address this fundamental problem, the proposed solutions are still limited since the energy that is replenished is either uncontrollable (such as environmen-

tal harvesting approaches) or require the nodes to be accessible by people or robots in a very accurate way (such as battery replacement approaches).

However, the breakthrough of wireless energy transfer technology (see e.g. [2]) combined with rechargeable batteries with high energy density and high charge/discharge capabilities [3], has managed to directly address energy management and led to the paradigm of Wireless Rechargeable Sensor Networks (WRSNs). In such networks, special entities (called Chargers) are able to charge sensor nodes wirelessly. This procedure is called wireless charging. Thus, the limited available energy can be managed in a controllable and more efficient manner. This option introduced some new aspects that need investigation such

22 as how Chargers should be deployed, how much energy
23 each Charger should transfer to each sensor node or what
24 is the minimum number of required Chargers in order to
25 improve network properties such as lifetime, connectivity
26 and coverage.

27 Another critical aspect that needs investigation is the
28 effect of the exposure on the electromagnetic radiation, oc-
29 curred by wireless energy transfer, in human health. Wire-
30 less charging may address more efficiently the problem
31 of limited energy with respect to network properties if
32 we use Mobile Chargers instead of simple Chargers. Mo-
33 bile Chargers are called the devices which are able to both
34 charge sensor nodes wirelessly and move throughout the
35 network. This new capability introduced some additional
36 options that need investigation such as how Mobile Charg-
37 ers can coordinate or which is the trajectory that each Mo-
38 bile Charger should follow.

39 The collaborative mobile charging approach proposed in
40 [4] offers even more useful options. In this new charging
41 method, Mobile Chargers are allowed to charge not only
42 sensor nodes but also other Mobile Chargers. This new ca-
43 pability has been proven very important, since it provides
44 better exploitation of the potentially limited available en-
45 ergy supplies.

46 *The problem.* Let a WRSN comprised of stationary sen-
47 sor nodes and Mobile Chargers that can either charge the
48 nodes or charge each other (collaborative charging). The
49 transformation of the flat collaborative charging scheme
50 to a hierarchical one (hierarchical, collaborative charging)
51 imports new challenges for the network energy manage-
52 ment. We aim at designing efficient protocols for the Mo-
53 bile Chargers' coordination and charging procedure, in or-
54 der to efficiently distribute and manage the available finite
55 energy, prolong the network lifetime and improve key net-
56 work properties such as coverage, routing robustness and
57 network connectivity.

58 *Our contribution.* Since collaboration provides an effi-
59 cient energy management potential, we envision collab-
60 oration in a hierarchical structure. More specifically, we
61 propose a partition of Chargers into two groups, the hier-
62 archically lower Mobile Chargers, that are responsible for
63 transferring energy only to sensor nodes and the hierarchi-
64 cally higher Special Chargers that are responsible for trans-
65 ferring energy to Mobile Chargers. Using our hierarchical
66 charging model, we first propose a protocol for 1-D net-
67 works that achieves a better performance ratio than known
68 state of the art protocols, when the available energy sup-
69 plies are limited.

70 Motivated by the improvement in 1-D networks we
71 propose four protocols for 2-D networks as well. Our pro-
72 tocols differ on the available network's knowledge level
73 (2-level knowledge, 1-level knowledge and no knowledge)
74 as well as on their coordination procedure (distributed or
75 centralized). Our No Knowledge No Coordination (NKNC)
76 protocol actually serves as a performance lower bound
77 since it assumes no network knowledge and does not per-
78 form any coordination. In contrast, our 2-Level Knowl-
79 edge Centralized Coordination (2KCC) protocol assumes 2-
80 level knowledge and performs centralized coordination.
81 In between, our 2-Level Knowledge Distributed Coordina-
82 tion (2KDC) and 1-Level Knowledge Distributed Coordina-

tion (1KDC) protocols both perform distributed coordina- 83
tion but, since they assume different knowledge level, their 84
coordination and charging procedures differ. 85

86 Moreover, the hierarchical solution that we provide can
87 be easily added on top of non-collaborative protocols to
88 further improve their performance (by applying the neces-
89 sary transformations which depends on the existing charg-
90 ing model). In particular, we enhance a known state of
91 the art protocol that does not use any collaboration, by
92 adding a hierarchical collaborative charging structure and
93 we show the added value of hierarchy.

2. Related work and comparison 94

95 Wireless energy transfer technology inspired a lot of
96 researchers to investigate how to exploit it in WSNs effi-
97 ciently. In [5], the authors used a realistic scenario where
98 the sensor nodes are mobile and the Chargers are station-
99 ary. They proposed two protocols to address the problem
100 of how to schedule the Chargers activity so as to maximize
101 either the charging efficiency or the energy balance. Also,
102 they conducted real experiments to evaluate the protocols'
103 performance. In [6], the objective was to find a Charger
104 placement and a corresponding power allocation to max-
105 imize the charging quality. They proved that their problem
106 (called P^3) is NP-hard and proposed two approximation al-
107 gorithms for P^3 (with and without fixed power levels) and
108 an approximation algorithm for an extended version of P^3 .

109 However, the exposure on the electromagnetic radia-
110 tion that is caused by wireless energy transfer may lead
111 to undesired phenomena for human health. That is why
112 there are a lot of works that investigate this aspect and
113 try to control the electromagnetic radiation. More specifi-
114 cally, in [7] the authors studied the Low Radiation Efficient
115 Charging Problem in which they optimized the amount of
116 "useful" energy that is transferred to nodes with respect
117 to the maximum level of imposed radiation. In [8], the
118 authors investigated the charging efficiency problem un-
119 der electromagnetic radiation safety concern. More specifi-
120 cally, they formulated the Safe Charging Problem (SCP) of
121 how to schedule the Chargers in order to increase the re-
122 ceived power while there is no location in the field where
123 the electromagnetic radiation exceeds a threshold value.
124 They proved the hardness of SCP and proposed a solution
125 which outperforms the optimal one with a relaxed thresh-
126 old. Also, to evaluate the effectiveness of their solution,
127 they conducted both simulations and real experiments.

128 The same research group in [9] studied the Safe Charg-
129 ing with Adjustable Power (SCAPE) problem which refers
130 on how to adjust the power of the Chargers in order to
131 maximize the charging utility of the devices while assuring
132 that electromagnetic radiation intensity at any location on
133 the field does not exceed a threshold value. They also pro-
134 posed an $(1-\epsilon)$ -approximation algorithm for the problem
135 and conducted simulations and real experiments to evalu-
136 ate the algorithm's performance.

137 Although all above works have studied a variety of
138 problems caused by wireless energy transfer and try to
139 maximize the received power by the sensor nodes under
140 various constraints, the usage of stationary Chargers does
141 not exploit all the capabilities of the technology. The hard-
