This is a PDF file of an unedited manuscript that has been accepted for publication. As a service to our customers we are providing this early version of the manuscript. The manuscript will undergo copyediting, typesetting, and review of the resulting proof before it is published in its final form. Please note that during the production process errors may be discovered which could affect the content, and all legal disclaimers that apply to the journal pertain.

Highlights

- Fully automated segmentation for a hip joint is proposed as an unsupervised method, using the complementary characteristics between the patient-specific optimal thresholding and the watershed algorithm.
- The patient-specific optimal thresholding, which is determined by the golden section method and load path algorithm, provides regional information on the femur but may offer its disconnected boundaries.
- The watershed algorithm always offers closed patches but does not offer regional information on the femur.
- Clinical case studies with eight sets of CT scan data demonstrated that the proposed method can segment a hip joint as fast as automated segmentation methods while maintaining the segmentation accuracy at the level of semi-automated methods without the aid of a prerequisite training dataset and user intervention.
